By Dr. C. J. Smith. Fourth edition. Pp. xiii + 1322. (London: Edward Arnold (Publishers), Ltd., 1957.) 45*s.* net.

OVER some twenty-five years the successive editions of this standard intermediate text-book have proved their value. There are 300 more pages than in the 1947 edition, and the extensive re-writing to clarify points which students always find difficult, with the addition of material to bring it well up to the requirements of a good scholarship candidate, will certainly increase even further the number of people who will use it happily and with success. Noteworthy additions are the fuller treatment of

RADIATION

Čerenkov Radiation

By **J. V. JELLEY,** B.SC., PH.D., *Atomic Energy Research Establishment, Harwell*

From the earliest days of the history of radioactivity, it was noticed that various substances emitted a feeble light under the influence of radiations from radioactive substances, and this, in course of time, was found to be fluorescent light. Čerenkov discovered in 1934 that a very weak solution was visible even from pure liquids, and a detailed study of a large variety of pure liquids led him to the conclusion that this new phenomenon was of a different nature from that of fluorescence. The effect, which soon became named after him, was three years later interpreted by Frank and Tamm (1937) on the basis of classical electromagnetic theory.

ČERENKOV RADIATION is an up-to-date review of the theory, together with details of experimental work and applications, by one of the experts on the subject—Dr. J. V. Jelley, of Harwell. This is the only monograph devoted exclusively to the subject of Čerenkov radiation and its applications.

Atomic Radiation and Polymers

By **A. CHARLESBY,** D.SC.

Although it is only a few years since the discovery that many materials could be improved by subjecting them to radiation, rapid advances have taken place in this new field, and commercial applications are already appearing. One of the most promising applications arises in the field of plastics, whose properties can be greatly improved. This volume reviews the many scientific papers and short articles that have been published and covers the changes produced in materials by atomic radiation from reactors, or by electron radiation from high voltage sources. *This is the first book to be published in this field,* and Dr. Charlesby has started from basic principles and developed up to the most advanced work carried out on the subject.

ATOMIC RADIATION AND POLYMERS presents present-day knowledge both to scientists and engineers working in the field of nuclear energy and to polymer chemists interested in applying this new technique to the modification of their materials.

In preparation

Chronic Radiation Hazards

By **G. J. NEARY, R. J. MUNSON,** *and* **R. H. MOLE,** *Medical Research Council Radiobiological Research Unit, A.E.R.E., Harwell.*

This monograph reports the results of an investigation of the biological effects of chronic irradiation, in which mice were irradiated with fast neutrons up to normal life span. Full biological and physical details of the experiments are given, including a discussion of the dosimetry. The results include data on survival, body weight, pathology, haematology, organ weights and fertility. This is an important book for all concerned with aspects of nuclear energy and the biological sciences, as well as medical workers concerned especially with radiotherapeutics.

VACUUM GAUGES

we have progressed since *McLeod*

it is now Kammerer

The new Kammerer Vacuum Gauge applies the same principle as the McLeod Vacuum Gauge, but it has been designed in accordance with modern engineering methods giving the following advantages.

★ Small, handy apparatus ★ Lowest possible mercury filling
★ Facilitates easy and quick measurement

For further information regarding this equipment, please send your enquiries to Leybold Vacuum Sales, Ltd., Dept. N.P.

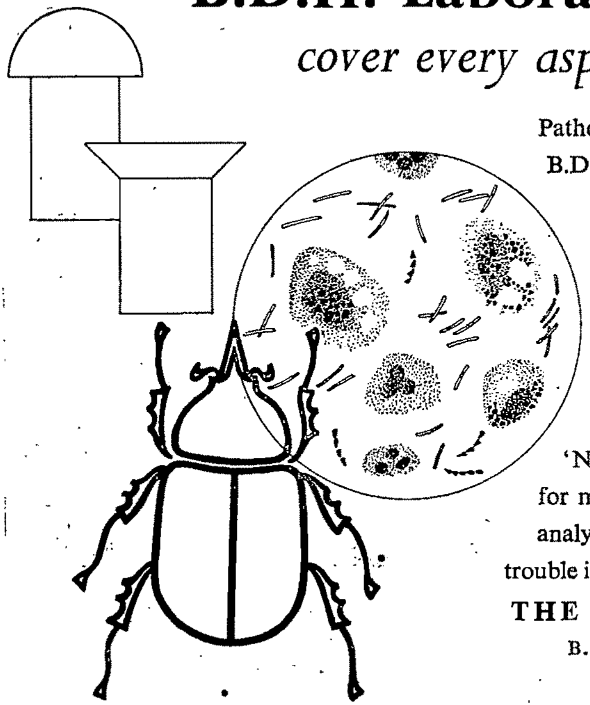
B.D.H. Laboratory Chemicals

cover every aspect of laboratory practice



Pathologist, analyst, metallurgist, schoolmaster—each finds the B.D.H. catalogue equally useful. The six thousand laboratory chemicals it contains range from sugar phosphates to technical dyes, from indicators to micro-analytical reagents, from microscopical stains to Jet-test solutions. It covers every field in which practical work is carried out in chemical laboratories.

Stabilized Raney nickel catalyst, concentrated volumetric solutions, tablets for Kjeldahl determinations, 'Narrow Range' and 'Wide Range' indicator papers, tablets for milk testing and prepared reagents for general and clinical analysis are typical of special B.D.H. items that save time and trouble in the laboratory.

THE BRITISH DRUG HOUSES LTD.
B.D.H. LABORATORY CHEMICALS DIVISION
POOLE DORSET

LC/P/16c

dynamics and of the experimental side of electrostatics, and a chapter on forced vibrations and resonance in the section on acoustics. There are also many more numerical examples for solution.

Dr. Smith holds strong views about the MKS system, which one gathers he would not touch with a pole; and his comment on units in the preface may seem a little sweeping. His mastery of the orthodox approach in the sections on electricity, and the general excellence of its presentation, nevertheless compel one's admiration. G. R. NOAKES

Principles of Engineering Heat Transfer

By Prof. Warren H. Giedt. Pp. xiii+372. (Princeton, N.J., and London: D. Van Nostrand Company, Inc., 1957.) 48*s*. net.

IN view of the extensive literature of the subject, the number of text-books on heat-transfer is surprisingly few and makes this new addition especially welcome. The author has rightly devoted the major part of the work to a fundamental exposition of the basic principles, avoiding embroilment in the jungle of empirical data which has grown up with the development of this subject. The book follows the natural division of heat-transfer into the three modes of conduction, convection and radiation, all of which are treated with admirable clarity. The order of treatment is, however, somewhat unusual, the separation to opposite ends of the book of the chapters on steady-state and transient conduction appearing to serve no useful purpose. The relegation to the last chapter of the concept of logarithmic mean temperature difference, which is so fundamental in the study of heat-exchange equipment, is also a less desirable feature of the book. Convection is preceded by two chapters on fluid flow which in the main are most helpful to an understanding of convective heat-transfer principles. There are, however, certain superfluities for a book of this kind, the most noticeable of which is the inclusion of the elementary theory of orifice and venturi meters.

Among the commendable features of the book are the summary of the principles of the heat and momentum transfer analogy in the solution of turbulent convection problems, including the extension to the special problem of liquid metals, and the description of electric analogue methods in the solution of conduction problems.

The book will be extremely useful to the student at university degree-level but would have been improved by the inclusion of numerical answers to the many end-of-chapter problems, a deficiency which, alas, is a common failing of almost every text-book of American origin. H. COHEN

Die Bluteiweisskörper des Menschen

Untersuchungsmethoden und deren klinischpraktische Bedeutung. Von Prof. Ferdinand Wuhrmann und Dr. Charlie Wunderly. Dritte völlig umgearbeitete Auflage. Pp. 499. (Basel und Stuttgart: Benno Schwabe and Co., 1957.) 52 Swiss francs.

THE previous two editions of this treatise, published in 1947 and 1951, were, perhaps, much better known on the Continent than in Britain because no English versions were available. This edition is an extensive revision and enlargement of the former editions. A welcome feature is the prominence now given to paper electrophoretic and agar gel immuno-electrophoretic techniques. Here, at last, is a book which brings together so many illustrations of abnormal plasma protein patterns. Another feature is the thorough discussion of the traditional techniques of free electrophoresis, ultracentrifugation and salting out. Routine clinical methods for blood examination are also well covered; the clinical significance of the plasma proteins, their evaluation and their alteration in disease are comprehensively discussed.

There is a tendency, perhaps understandable, to refer more to German than to non-German sources, but consequently some important work is overlooked or not given the attention it deserves. Recent techniques of zone electrophoresis in columns or slabs or of ion exchange chromatography are not mentioned though they have been used with striking success for plasma protein separation. In such a detailed book the subject index might perhaps be fuller. However, there is a good balance between the physico-chemical and clinical sides and in this respect the book is exceptional. Each of the authors is a specialist in each field and they have collaborated for many years in clinical investigations. Though rather expensive the price is not too high for such an attractively printed, comprehensive reference work. Its appeal would undoubtedly be widened if an English version was available. R. CONSDEN

Selected Lectures in Modern Physics for School Science Teachers

Edited by Prof. H. Messel. Pp. 168. (Sydney: Nuclear Research Foundation within the University of Sydney, 1958.) 30*s*.

IN January of this year the Nuclear Physics Foundation of the University of Sydney held a summer school for science teachers. This was not just a refresher course to attack or remove the outer layers of rust. Its expressed intention was to infect the participants with an inspiration which they would spread, and the direct aim a second-order effect on the future entrants to the faculties of science and engineering. This record of the proceedings, which was made available at the end of the school (in itself a remarkable feat of publishing), is both a worthy tribute to the venture itself and an excellent survey of many fields of modern physics.

The twenty-four lectures range widely, and the topics seem to have been chosen for their general interest; they are the matters on which a teacher would very properly be expected to be able to answer questions. Nuclear energy; low-, high-, and ultra-high energy nuclear physics; 'strange' particles; physics in rain-making; Newton's laws of motion and space-travel; radioastronomy; how to talk to an electronic brain; transistors; the use of isotopes in medicine; physics in geology; measurement; and cosmic radiation; these are among the main subjects selected. There are also an instructive account of the building of relatively simple apparatus for demonstration experiments in electronics and nuclear physics, and a discussion of careers in physics, and of the need of suitable candidates for them.

The lecturers themselves are to be congratulated on touching just the right level for their audience, and on communicating their obvious enjoyment of their work. I learned a great deal from the book, felt that I understood most of it, and was much impressed by the way it was all presented. The book can be highly recommended to teachers of science, and will be a most valuable acquisition to a school science library. G. R. NOAKES

THE LYOT $H\alpha$ HELIOGRAPH AT THE CAPE OF GOOD HOPE

By DR. M. A. ELLISON

C.S.A.G.I. Reporter for Solar Activity, Royal Observatory, Edinburgh

THE organization of the International Geophysical Year has provided a splendid impetus to the study of solar-terrestrial relations. Quite early in the planning stages it was realized that the solar chromosphere must be kept under continuous observation throughout the eighteen months. This meant the provision of equipment, well distributed in longitude and located in the most favourable climates, which would automatically photograph the Sun in hydrogen light at 1-min. intervals. In addition, the observing periods at existing stations, equipped with visual spectrohelioscopes, had to be planned in advance on a time basis so as to fill in the gaps and avoid duplication[1].

This organization has become known as the 'solar patrol'. Some 25 stations are now filming the Sun, and by their combined efforts it is hoped that no solar activity which may be of significance in the study of the ionosphere, geomagnetism, cosmic rays or solar radio emission, will pass unobserved.

In the middle of 1955, the British National Committee for the International Geophysical Year decided to make a substantial contribution to the work of the solar patrol. A sum of £17,000 was voted for the provision of a Lyot-type heliograph along with some auxiliary apparatus and the building to house it. The site chosen was the Royal Observatory, Cape of Good Hope, where under Her Majesty's Astronomer (Prof. R. H. Stoy), expert staff and maintenance facilities would be available. The sunshine hours at the Cape average 68 per cent of possible, compared with some 40 per cent in the most favourable part of the British Isles. For many years the Cape Observatory has contributed daily photographs of the Sun in white light to the Greenwich photoheliograph programme; and in 1949 the Sun was photographed at the Cape on 360 days.

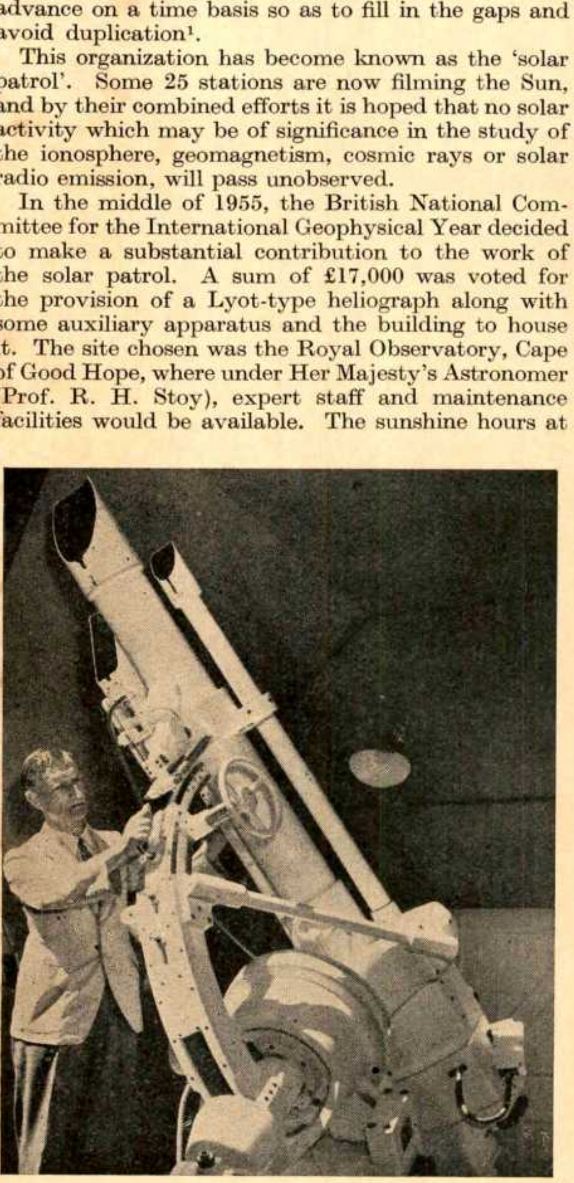


Fig. 1. Lyot $H\alpha$ heliograph installed at the Royal Observatory Cape of Good Hope

The contract for the construction of the heliograph was placed by the Admiralty with the firm Société d'Études et de Construction d'Appareillages Scientifiques et Industriels of Bordeaux in December 1955. The completed instrument was accepted there in November 1957 and delivered to the Cape on February 25, 1958. After successful tests of the optics and electronic circuits, it was brought into daily operation on March 16.

We owe the original conception of the monochromatic heliograph to the late Bernard Lyot. After his lamented death in 1952, the plan was brought to a practical outcome by the construction of a prototype instrument at Meudon, chiefly through the labours of the d'Azambujas and Dr. A. Dollfus. The production on a commercial basis was undertaken by the Société d'Études et de Construction d'Appareillages Scientifiques et Industriels, the study group of which was responsible for the equatorial mounting, the electronic and electro-mechanical arrangements, as well as the auxiliary and cinematograph optics. The main objective and the monochromatic filter were constructed by the firm Optique et Précision de Levallois.

The instrument comprises three separate optical trains. In the centre (Fig. 1) is the monochromatic telescope, consisting of an objective of 14 cm. aperture working at f 10. The beam from this lens traverses two glass prefilters before being rendered parallel for its passage through the Lyot filter. This filter is of the standard design[2], being built up of eight birefringent plates of quartz and others of calcite with intermediate 'Polaroids', all contained inside a cylindrical block of aluminium. The temperature of the block is thermostatically controlled so that at the working temperature of the filter (44·2° C.) the band pass of 0·7 A. is maintained precisely fixed upon the centre of the $H\alpha$ line (6562·8 A.). On emerging from the filter, the monochromatic beam is focused on the film frame of the camera placed in the breech of the telescope and forms there a solar image 15 mm. in diameter. Exposures are made on standard 35-mm. film; using Kodak Panchromatic Microfile emulsion, the normal exposure time is 2 sec. The duration between exposures may be pre-selected for intervals of 60, 30 or 15 sec. By the operation of a uni-selector switch every eleventh frame receives an exposure time five times normal. This has the effect of over-exposing the disk so as to record only the prominences at the Sun's limb. An eye-piece conveniently placed at the side of the camera allows the image in $H\alpha$ to be observed visually in the intervals between exposures.

The second optical train (right-hand tube of Fig. 1) is that of the electronic guider and exposure meter. The main drive to the equatorial in right ascension is provided by a synchronous motor which operates

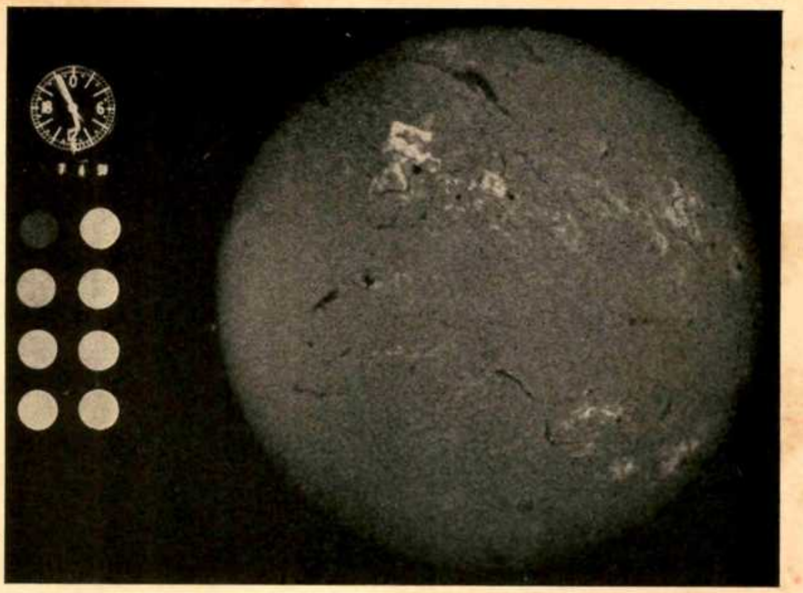

Fig. 2. Heliograph exposure, April 7, 1958, 10h. 55m. 54s., showing a Class 3 flare in operation. Normal sky orientation

through the usual reduction gear, worm and driving wheel. The electronic guider compensates for all errors in the main drive, for maladjustments of the polar axis and for refraction changes at varying altitudes. The image to be photographed is thus maintained centred in the film frame with an accuracy of 1–2 sec. of arc —an important feature when the films are to be examined later with a cinematograph projector.

The lens system of the guider forms a solar image about 1 in. in diameter. This image illuminates a wide slit tangential to the east limb together with a circular hole placed some distance inside the west limb ; the slit has an aperture twice the area of the hole. When the light flux through each is the same, the photocells behind receive equal illumination and their currents cancel one another. An excess of current in either direction, due to a lateral shift of the image, operates a symmetrical valve amplifier the output of which affects a magnetic amplifier with two stages. This, in turn, operates in either sense the diphase motor of the right ascension slow-motion. A similar arrangement of apertures and photocells, placed at right angles to the former pair, corrects for errors in declination. Such a system has the added advantage that it functions independently of the seasonal variations in the apparent diameter of the solar image.

In the same optical system the centre of the solar image illuminates a small aperture behind which is placed a fifth photocell. This cell acts as a photometer and regulates the duration of each exposure. The start of the exposure is obtained by applying a negative charge to the condenser of a light-integrator, which, by means of a valve $6AK5$, releases the trigger of the camera shutter. The condenser is progressively discharged by the cell of the photometer. When the condenser has discharged, the same valve again becomes conducting, pulling the shutter trigger and terminating the exposure. The exposure-times are thus proportional to sky opacity, which means that the resulting solar images on the film are of nearly uniform density, a most important feature for accurate photometry.

When thick cloud intervenes, a 'no light' relay comes into operation, switching off the camera action in order to conserve film. As the sky clears, the image is automatically re-centred and the operating cycle begins again.

The third optical system (to the left of the main tube in Fig. 1) serves two purposes. First, it contains a clock and calendar which are illuminated by diffuse sunlight. The clock is set to Universal Time at the start of each day's run, and its image, focused on the film by means of a lens-cum-prism train, records the time and date of each exposure (Fig. 2). Secondly, an echelon of eight circular spots is focused below the clock in order to provide a photometric calibration. The echelon is formed of eight blocks of neutral glass, each having been ground and polished to a suitable thickness so as to provide density steps of 0·1. These blocks are uniformly illuminated by direct sunlight which has previously traversed a red filter and an opal diffusing screen. Thus the quality of the light forming the calibration image on the film is similar to that of the solar image, while the exposure-time is the same for both whatever the transparency of the sky.

The equatorial mounting is of unusual design, having been planned with a short polar axis and a wide fork to combat the effects of flexure and wind vibration. Rising from the lower end of the polar axis are two telescopic arcs of radius 80 cm. which are concentric with the declination axis. The extension of these arcs by means of a rack and pinion provides for the seasonal variations of ± 23° in declination. The inner arc carries at its head the diphase motor and screw of the declination slow-motion, the upper end of the telescope tube being held in contact with the screw by means of two extensible springs. The telescope thus receives support from the three angles of an isosceles triangle.

A control cabinet for the instrument houses under damp-proof conditions the filter thermostat, the time-relays for operating the exposures and all the electronic and electro-mechanical parts. Controls are effected by press-buttons on the front panel, where indicator lamps also enable the operator to judge the correct functioning of the various circuits. Experience gained at the Cape fully supports the claim for automatic operation. Apart from the routine procedures of setting on the Sun, regulating the clock and loading the film cassettes, it performs its daily run without further attention until close-down. The roof of the building has been so constructed that a clear aperture extending across the sky is available at all seasons.

The films taken with the heliograph (about 25 ft. per day) are being developed at the Cape. They are then dispatched to the Royal Observatory, Edinburgh, where they are projected and examined for the occurrence of flares and blow-off prominences, the records of these phenomena being contributed monthly to the International Geophysical Year World Data Centres. The images on 'Microfile' film can be enlarged to a diameter of 6 in. before the film grain becomes noticeable ; and on this scale they show considerably greater resolution of fine detail than the best spectroheliograms.

The high performance of the filter is also illustrated by the low intensity of the scattered light. On a day of moderate sky transparency, the scattered light (sky plus instrumental) at a distance of 2 min. of arc outside the solar limb was measured as 3 per cent of the intensity of the central disk. With most spectrographs the scattered light would have five times this value. On the other hand, the intensity at the centre of the disk in the $H\alpha$ image was found to be 28 per cent of the intensity of the continuum outside the wings of $H\alpha$. This is high compared with the known value of 15 per cent for the centre of the $H\alpha$ line ; it arises from the relatively wide band-pass of the filter (0·7 A.), which causes it to transmit appreciable light from the line wings.

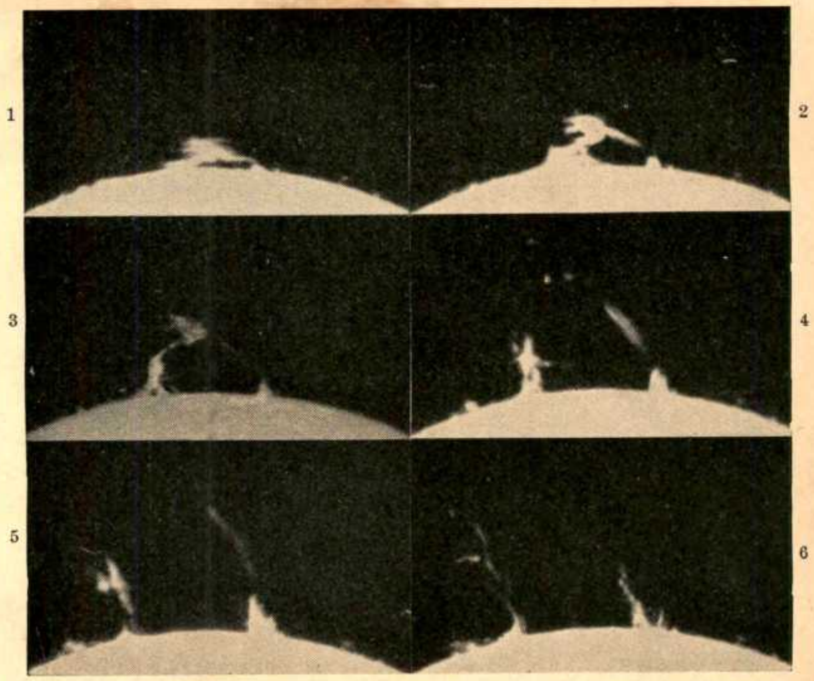

Fig. 4. Blow-off prominence on the west limb, March 14, 1958. Times: (1) 14h. 39m. 10s.; (2) 14h. 50m. 15s.; (3) 14h. 54m. 15s.; (4) 14h. 58m. 25s.; (5) 15h. 01m. 25s.; (6) 15h. 04m. 25s.

One of the most important investigations to be undertaken with the Lyot heliograph will be the photometry of solar flares. Accurate light-curves for these events are required so that we may be in a position to compare them with the development of: (1) the sudden disturbances in the terrestrial ionosphere, for example, geomagnetic crochets, radio fade-outs and sudden enhancements of atmospherics, which occur almost simultaneously; and (2) the 'outbursts' of radio emission which are generated in the flare regions. In Fig. 3 are plotted photometric light-curves for three distinct regions in a Class 3 flare which was recorded with the heliograph on April 7 (see also Fig. 2). One can observe here how the regions A and C, which were separated by 98,000 km. in the chromosphere, brightened up and reached their maximum intensity simultaneously. The development of the sudden ionospheric disturbance (recorded as a sudden enhancement of atmospherics on frequency 24 kc./s.) is shown in the same diagram. The time-lag of 12 min. between the peak intensity of the flare and that of the sudden ionospheric disturbance confirms the similar results previously obtained from visual records of flare line-widths made with the spectrohelioscope[3].

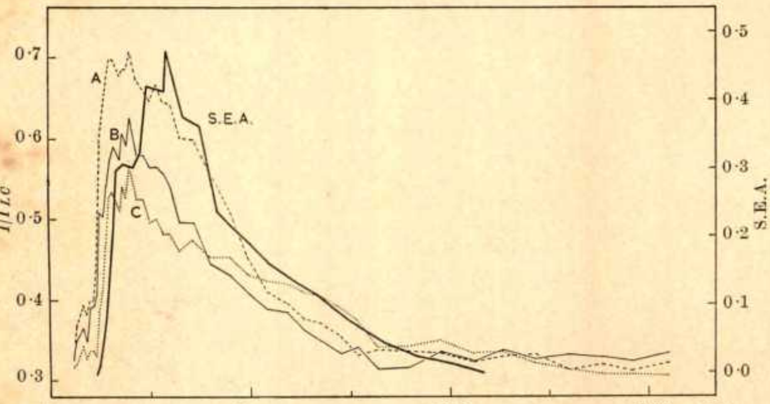

Fig. 3. Photometric light-curves plotted for three regions in the Class 3 flare of Fig. 2. Intensities are expressed in terms of the local continuum outside the wings of the $H\alpha$ line. The heavy line shows the development curve of the sudden ionospheric disturbance (recorded at Edinburgh as a sudden enhancement of atmospherics on a frequency of 24 kc./s.)

Lastly, in Fig. 4 we can see the great potentialities of the instrument as a means for providing a rapid sequence of pictures of prominence material blowing off into space at the Sun's limb. The top of this prominence arch rose through 180,000 km. in 19 min.; before it faded away, it was moving with a velocity of 625 km./sec. across the line of sight. Had the blow-off occurred near the centre of the disk, instead of at the limb, the sightline component of velocity would have shifted the prominence $H\alpha$ line some 14 A. to the violet, right outside the pass-band of the filter. The mechanism which leads to this sudden outward acceleration of solar material remains unsolved.

Three similar Lyot heliographs have been completed and delivered by the Société d'Études et de Construction d'Appareillages Scientifiques et Industriels. One has gone to Tokyo, another to Washington and the third to the McMath-Hulbert Observatory, Michigan. In the coming years we may therefore anticipate much fuller records leading to a more complete understanding of chromospheric activity; a happy situation that has been brought about largely through the inspiration and the funds of the International Geophysical Year.

LONG-RANGE TRAVEL OF THE RADIOACTIVE CLOUD FROM THE ACCIDENT AT WINDSCALE

By N. G. STEWART and R. N. CROOKS
Atomic Energy Research Establishment, Harwell

LOCAL air measurements made during the course of the accident on October 10, 1957, at Windscale No. 1 Atomic Pile showed that radioactivity was released into the atmosphere between noon on October 10 and noon on October 11 (ref. 1). Meteorological conditions throughout this period were complex. During October 10 a ridge of high pressure extended over England from the east, giving mainly light south to south-west winds. A shallow depression passed close to Windscale during the evening of that day, causing the local winds to back to an easterly direction and become very light for a few hours, after which the wind returned to its original south-westerly direction. During the day, the air in the lowest 400 ft. of the atmosphere was unstable, with an inversion above. By late evening, the air near the ground was stable.

Early on October 11, at about 0100*Z*–0200*Z*, a cold front, which during the previous day had been moving south-eastwards across Scotland, passed over Windscale. At the passage of the front the wind quickly veered to the northerly and increased to about 10 knots and slowly backed to north-west during the next twelve hours. The front reached London about 1330*Z* and cleared Britain by about 1900*Z* on October 11. Behind the front, the air was unstable up to about 4,000 ft., but by the evening of October 11 the lowest layers of the atmosphere had again become stable.

Cloud Sampling

As the radioactive cloud passed over the United Kingdom and Europe, samples of the airborne dust were collected on filter papers which had been exposed in many places for monitoring industrial smoke or the dust from nuclear test explosions. Most of these filters had been exposed for 24-hr. periods, but at a number of sites continuously moving strip filters had been used, and these provided a detailed picture of the passage of the cloud overhead.

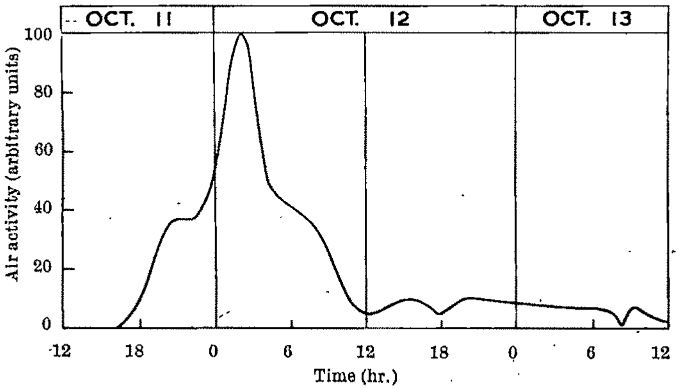

Fig. 1. Time variation of air activity at Harrow, Middlesex

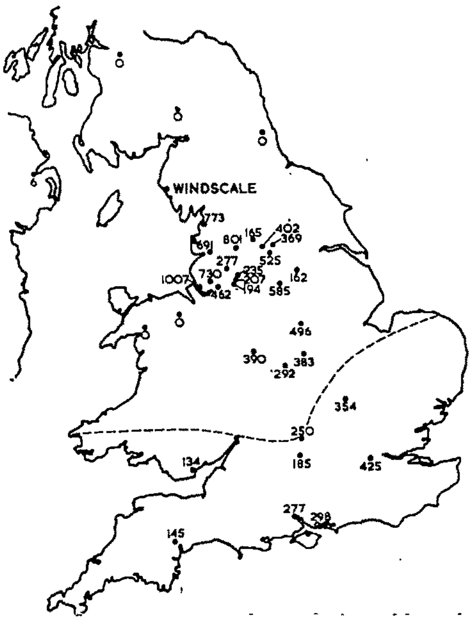

Fig. 2. Dosage of iodine-131 in air ($\mu\mu c$-days/m.^{3})

The majority of the samples from Great Britain were obtained from the public health departments of local authorities and from the Fuel Research Establishment by Mr. G. B. Courtier, of the Scientific Branch of the London County Council, who sent them to Harwell for detailed analysis. Many of the samples from Europe were obtained through the chairman of the International Geophysical Year Advisory Committee on Nuclear Radiation, Prof. W. Bleeker, who arranged for the filters exposed at routine sampling stations to be forwarded to Harwell for the measurements to be made on a common apparatus.

The results show that the cloud travelled ultimately in a south-easterly direction and had substantially passed over Lancaster by noon on October 11. It is possible to deduce from the 24-hr. samples in the Leeds–Bradford area that the cloud first reached there at about 0900*Z* on October 11 at the same time as the cold front, suggesting that this part of the cloud had initially travelled in a north-easterly direction on October 10 and had been afterwards swept southwards with the wind accompanying the front. The arrival of the cloud at Harrow, Middlesex, at 1600*Z* on October 11—some three hours after the cold front—is demonstrated in Fig. 1, which is taken from a record obtained by Dr. Herz, of Kodak, Ltd., using a moving-strip filter apparatus. The main part of the cloud passed over in about 20 hr., but low levels of activity persisted for

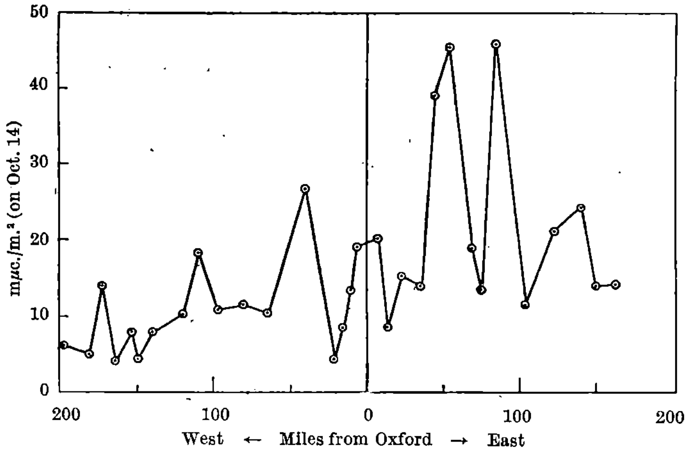

Fig. 3. Survey of iodine-131 on grass

another three days. The cloud first reached Mol (Belgium) at 1900*Z* on October 11, Frankfurt at 2200*Z* on October 12 and Sola (Norway) at some time on October 15.

Analysis of Radioactivity

The nature of the radioactivity was analysed radiochemically and by gamma-ray spectrometry, and the relative amounts of the main components on a filter exposed at Harwell (360 km. from Windscale) throughout the time of passage of the cloud are given in Table 1.

Table 1

Isotope	Half-life	Relative activity at 0001 hr. on October 11
Iodine-131	8 d.	100
Tellurium-132	77 hr.	85
Iodine-132	2·3 hr.	85
Cæsium-137	30 y.	11
Ruthenium-103	40 d.	7
Polonium-210	135 d.	2·6
Strontium-89	54 d.	0·8
Strontium-90	28 y.	0·04

The figures differ in some respects from those quoted by Chamberlain and Dunster[2] for a short-period air sample at Calder. In particular, the ratio of iodine-131 to cæsium-137 on the Calder filter was 38·5 as compared with 9·1 at Harwell. The mean value at ten sites in Great Britain south of Lancaster was 9·0 ± 1·8 (standard deviation).

The concentration of iodine-131 in the air at each sampling point has been integrated over the time of passage of the cloud to give cloud dosage figures expressed in μμc.-days/m.³. These have been plotted for the United Kingdom in Fig. 2, which shows that the cloud avoided north Wales but diffused to cover a wide front in the southern part of the country. The degree of dispersion is better shown in Fig. 3, which presents the results of a survey of the iodine-131 deposited on grass between St. David's and Cromer (dotted line in Fig. 2). It is clear that the dust cloud spread out into the North Sea and it was probably this part of it which reached Mol in Belgium some three hours after the first radioactivity reached London. The iodine-131 cloud-dosage figures observed in Europe are, as expected, smaller than those found in southern England, and some representative values are given in Table 2.

Table 2

Place	Iodine-131 dosage (μμc.-days/m.³)
Paris	2·7
Brussels	49
Eindhoven	31
Hanover	8·8
Potsdam	2·7
Vienna	1·0
Zug (Switzerland)	0·2
Hradec Kralove (Czechoslovakia)	small
Sola (Norway)	1·9

The significance of the iodine-131 cloud dosages may be judged from the fact that at the highest recorded dosage-level in Fig. 2, a child would have inhaled about 0·01 μc. of iodine-131; this is about 1 per cent of the amount it would have ingested by drinking milk at the control-level defined by the Atomic Energy Authority and afterwards ratified by the Medical Research Council[1].

Deposition of Radioactive Material

Little rain fell while the cloud passed over England, and the radioactive dust was deposited on grass mainly by turbulent diffusion and impaction. The relation between the concentration of any isotope in air and the amount deposited can be expressed in terms of a 'deposition velocity' defined by:

$$V_g = \frac{\text{amount of isotope deposited per unit area}}{\text{time integral of air concentration } (= \text{dosage})}$$

Values of V_g were determined at places where air and grass measurements were made reasonably close together. The mean value for iodine-131 obtained near Preston, Burnley and Sheffield was $V_g = 0{\cdot}30$ cm./sec., while that in southern England was 0·11 cm./sec. These values are lower than the experimental figure of 2·5 cm./sec. obtained experimentally by Chamberlain and Chadwick[2,3] at Harwell under adiabatic conditions but are qualitatively consistent with the stable air conditions which obtained during the passage of the cloud. The velocities of deposition of cæsium-137 and ruthenium-103 were less than 15 per cent of that of iodine-131; a similar difference between iodine-131 and other fission products has previously been observed by Megaw and Chadwick[4]. This preferential removal of iodine-131 from the cloud would be expected to affect the isotopic composition of the residual dust, and it is significant that the ratio of iodine-131 to cæsium-137, corrected for radioactive decay, decreased from its mean value of 9·0 in England to 5·2 in Germany and to 2·8 in Norway, where the cloud did not arrive until October 15.

We wish to acknowledge the co-operation of the many people in various European countries who collaborated in this investigation. We would also like to thank our colleagues at Harwell who analysed the samples, especially Miss E. M. R. Fisher and Mr. D. L. O. Humphreys.

DEPOSITION OF RADIOACTIVITY IN NORTH-WEST ENGLAND FROM THE ACCIDENT AT WINDSCALE

By A. C. CHAMBERLAIN
Atomic Energy Research Establishment, Harwell

AND

H. J. DUNSTER
U.K. Atomic Energy Authority, Risley

Emission of Activity

THE course of events during the accident to No. 1 pile at Windscale on October 10 and 11, 1957, has been described in the report of the Committee of Investigation under Sir William Penney[1].

On the afternoon and evening of October 10 there was calm weather with light variable wind. A cold front was approaching from the north-west. In advance of the front there was a south-westerly wind which had an estimated speed of 7 knots at 500 ft. This wind blew for about three hours only, and with the passage of the front at Windscale about 0100 hr. on October 11, it was succeeded by a stronger northerly wind backing north-west, which blew for the remainder of that day.

The pattern of fall-out along the Cumberland coast shows that most of the deposition occurred after the north-west wind became established. Since the emission was from a 400-ft. stack, and in the presence of hot gases, the degree of turbulence at different times, as well as the wind direction, was important in determining the areas of deposition of activity.

The materials readily available for determining the nature and pattern of the deposition of activity were filter papers through which air had been passed for monitoring purposes during the incident, and grass which had received fall-out activity. Areas of one or two square yards were closely cut from areas such as roadside verges not subject to grazing by cattle. The method of measurement mostly used was gamma spectrometry. The samples were weighed and mixed, and aliquots of about 100 gm. wet-weight placed in polyethylene bottles on the crystal of the spectrometer under reproducible geometrical conditions. It was thought undesirable to dry the grass before estimating the iodine activity, lest some be lost by volatilization, although in fact no such loss was observed when samples were left exposed to the air. The dried weight of some samples was estimated by drying other aliquots. Calibration for the various nuclides was achieved by adding known amounts of activity to similar materials, and counting them under the same geometry. To enable the amounts of nuclides other than iodine to be measured, the analysis of many samples was repeated during December, by which time the iodine-131 had decayed. Details are given elsewhere[2].

Of the minority of fission products which do not emit gamma-rays, strontium-89 and strontium-90 were of obvious importance, and radiochemical analyses for these isotopes were performed.

In the first column of Table 1 are shown the activities of various nuclides, relative to iodine-131, on an air filter operated from 1000 hr. to 1030 hr. on October 11, at Calder Works, 800 metres south-east of Windscale Pile No. 1. Five cubic metres of air were drawn through the filter, and the iodine-131 activity on it was 5 μc. Also in Table 1 are shown the relative activities corrected to October 11, on samples of grass taken on October 13 at Seascale and Drigg, 3·2 and 6·4 km., respectively, south-east of Windscale. The iodine-131 activity of the Seascale sample extrapolated to October 11 was 0·16 μc./gm. dry-weight, and that of the Drigg sample 0·04 μc./gm. dry-weight. These results are similar to those of Kimber and Booth[3], who found 0·08 μc./gm. dry-weight in grass from a point 4·8 kilometres south of Windscale.

Table 1. ACTIVITY RELATIVE TO IODINE-131 OF FILTER PAPER AND GRASS SAMPLES

Nuclide	Air filter (Calder)	Grass	
		(Seascale)	(Drigg)
Iodine-131	100	100	100
Cæsium-137	2·6	1·2	2·0
Strontium-89	1·0	0·2	0·2
Strontium-90	0·02	0·004	0·01
Barium-140	2·5	—	0·5
Ruthenium-103	3·8	1·5	1·7
Zirconium-95	0·3	0·2	0·3

Small traces of other isotopes such as cerium-141, cerium-144 and ruthenium-106 were also detected.

The nuclides listed in Table 1 do not include those of short half-life; for example, tellurium-132 and its daughter product iodine-132. The presence of short-lived activities contributed appreciably to the gamma dose-rate immediately after the incident, but they were not important from the biological point of view.

Not all the fission products present in the grass were due to the Windscale incident, since all samples contain activity due to fall-out from distant bomb tests. Foliar contamination from this cause is thought to account for a considerable fraction of the activity of the non-volatile fission products such as zirconium-95 found in the grass.

The degree to which the more volatile fission products were enhanced in the activity emitted is illustrated by the ratio of iodine-131 to strontium-89. In long-irradiated fuel these nuclides are in the ratio 100 : 160, so that Table 1 shows that the escape of strontium-89 was less than 1 per cent of that of iodine-131, relative to the amounts in the pile.

Radioautographic examination of filter paper and other surfaces exposed to fall-out showed that most of the radioiodine was in gaseous form or absorbed on very small particles. Negligible amounts of uranium were disseminated in the accident, but some particles believed to be graphite with absorbed fission products were found both on air-filter papers and on the ground close to the pile. An extreme example was a 15-micron particle containing 0·8 μc. of barium-140, 0·4 μc. of strontium-89 and 0·01 μc. of strontium-90, with their daughter products, but no other detectable fission product activity. There

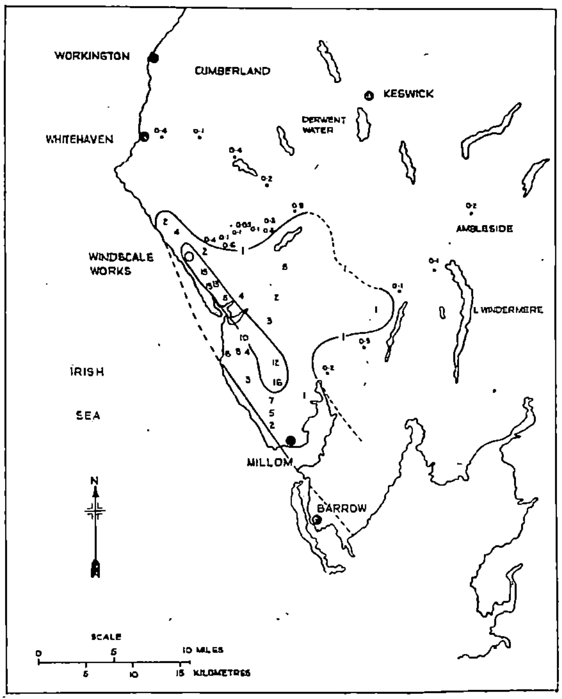

Fig. 1. Contours and spot-levels of iodine-131 activity on grass in μc./m.^{2} on October 11, 1957

evidently had been a physical separation of the elements barium and strontium, the boiling points of which are 1,140° and 1,150° C., respectively, from other fission products.

Other particles were found with activity due largely to cæsium-137. The activity associated with particles distinguishable by autoradiography or by the survey of surfaces with beta counters was, however, small in comparison with the total activity on the surface, and this was still true when measurements were repeated after the iodine-131 activity had decayed.

Deposition of Iodine-131

The fall-out pattern in Cumberland is shown in Fig. 1. The iodine-131 activity of grass has been worked back to October 11 by using the results at a location where repeated samples were taken. These showed that the activity in cut samples expressed in microcuries per square metre (μc./m.^{2}) decayed with an effective half-life of 5 days due to the combination of radioactive decay and other factors. Many more results are available than can be inserted in the figure[2].

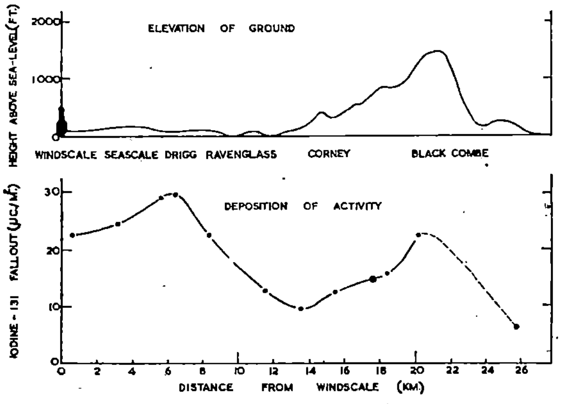

Fig. 2. Deposition of iodine-131 as a function of distance and elevation along line bearing 145° from Windscale

There is a narrow strip along the coast in which the contamination of the grass initially exceeded 10 μc./m.^{2}, but the 1 μc./m.^{2} contour extends to the Westmorland border and into the Barrow peninsula.

Theoretical relationships have been established between the amount of iodine-131 deposited and the dose-rate from the gamma-rays which are emitted[5]. Using these relations, measurements of gamma dose-rate have been used to derive estimates of the iodine-131 activity per unit area of ground, with results that agree quite well with the direct measurement of the activity of the grass. For example, at Seascale the iodine-131 activity in grass on October 11, from the sample of Table 1, was 15 μc./m.^{2}, whereas the activity deduced from the gamma dose-rate at a nearby point was 17 μc./m.^{2}.

The deposition of iodine-131 along the axis of the fall-out plume south-east from Windscale, estimated in this way, is shown in Fig. 2. There is a maximum of fall-out at Drigg, 6 km. from Windscale, and another on the slopes of the mountain Black Combe, 18 km. away. The second maximum was probably due to the elevation of the ground and the associated turbulence in the air over it, which would increase the transfer of activity to ground level.

Biological Implications

The results reported here were obtained with the aim of evaluating the physical processes affecting the released radioactivity. The greater part of the survey work following the accident was, however, concerned with assessing the magnitude and extent of the danger to man. This work was concentrated on human foodstuffs such as milk, eggs, meat, drinking water and vegetables; and it confirmed the conclusions reached from previous experimental work and theoretical assessments that iodine and strontium isotopes in milk would be the limiting contaminants. In fact, the preferential release of iodine relative to strontium made iodine the only material of biological significance.

An empirical correlation of the activities of milk and grass showed that about 10 μc./m.^{2} of iodine-131 on grass was required to give 1 μc./litre of milk. In order to protect children, milk supplies were condemned for human consumption in an area where any of the samples showed contamination of 0·1 μc./litre or more. The limit of this area followed roughly the 1 μc./m.^{2} contour of Fig. 1. It was not found necessary to impose any restriction on other foodstuffs.

A more detailed report of the surveys of milk and other foodstuffs will be published separately[4].

The collection and analysis of samples was done by many members of the staff of the Atomic Energy Authority both at Windscale and Harwell. We are especially grateful to H. Howells, W. L. Templeton, F. J. Woodman and A. E. Ross at Windscale, and to D. V. Booker, F. J. Bryant, W. H. Hardwick and M. J. Heard at Harwell.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

New President

SIR JAMES GRAY, professor of zoology in the University of Cambridge, has been elected president for 1959 of the British Association for the Advancement of Science in succession to Sir Alexander Fleck.

Sir James has had great influence on the course that zoology has taken in Great Britain. All who were concerned with the development of the experimental approach to the study of animals which occurred in the years following the First World War would regard James Gray as the leader, and his books on ciliary action and on experimental cytology as milestones along a broadening road of achievement. The interest in movement revealed in the former led to enrichment of knowledge in a series of admirably planned and beautifully executed researches on locomotion in segmented worms, in fish and in higher vertebrates.

Early in his history he assumed the editorship of *The Journal of Experimental Biology*, which he held for thirty years, establishing it as a major scientific journal and coming in this capacity to guide the work of a whole generation of younger workers. His achievements at Cambridge are there for all to see, not least in the high distinction of his colleagues in the Department. The Marine Biological Laboratory, Plymouth, owes much to him, from the stimulus of his presence as a young research worker to the culmination of influence as president of the Marine Biological Association. He is a trustee of the British Museum, has served on the Agricultural Research Council and on many other bodies, but with little doubt would put first among these his continuing responsibilities as a Development Commissioner and as the chairman of its Fishery Advisory Committee. Few with his distinction in the field of fundamental research have encountered more widely the implications of science on human welfare.

New Officers

Lord Rennell of Rodd succeeds Mr. Maurice G. Bennett as general treasurer of the British Association. Lord Rennell's scientific interests are mainly geographical and in 1922 and 1927 he carried out explorations in the Sahara. He was president of the Royal Geographical Society in the immediate post-war period 1945–48 and did much to revive and expand the activities of the Society. He has been largely responsible for organizing the appeal for additional funds on behalf of the British Association, and the measure of his success is obvious in the number of new fields in which the Association is now operating.

Dr. Norman Wright has been elected biological general secretary of the Association in succession to Dr. George Taylor. Dr. Wright is chief scientific adviser (food) to the Ministry of Agriculture, Fisheries and Food, and he is distinguished for his contributions to research in animal ecology and the application of nutritional science to human welfare. He was the first director of the Hannah Dairy Research Institute, Ayr, where he was charged with determining the design and layout of the new buildings and initiating the research programme. He is a member of a number of important committees concerned with food and agricultural matters and has served on the Agricultural Research Council. He has travelled widely on advisory missions. At the invitation of the Governments, he has reviewed the cattle and dairy resources of India, Pakistan and Ceylon, and also the animal industry in the Middle East. He is chairman of the Programme Committee of the Food and Agriculture Organization in Rome and in 1952 he was president of Section *M* (Agriculture) of the British Association.

Soddy Commemoration Plaque

The Soddy Commemoration Plaque in the Chemistry Department of the University of Glasgow was unveiled on August 27. Sir Hector Hetherington, vice-chancellor and principal of the University, presided at this occasion. He welcomed some relatives of Prof. Soddy who were in attendance and Prof. H. J. Emeléus, who represented the Royal Society. He then read a complimentary telegram from the Nobel Foundation, Stockholm. Sir Alexander Fleck, with a wise, reminiscent and affectionate speech, unveiled the bronze plaque with its portrait in relief and the citation "With Rutherford he shared the discovery of atomic disintegration, with Ramsay the proof of helium production from α-particles. In this Department he formulated his conception of isotopes". Prof. J. Monteath Robertson, in accepting the memorial tablet, thanked Mr. James Barr, the artist, and also Dr. Andrew Kent, who had organized the proceedings and also a Soddy exhibition including the original piece of isotopic lead—208—which had been loaned by Prof. McNeill of Toronto.

FREDERICK SODDY, M.A., LL.D., F.R.S.

A photograph (R. Cowper) of the plaster-cast by James Barr, D.A., for the memorial plaque in the Chemistry Department, University of Glasgow. It is based on photographs of or about his Glasgow period (1904–14) and on the Cannizzaro medal by "T.S.S.".

Endeavour Prizes

The prizes awarded for the 1958 *Endeavour* Essay Competition were presented by Sir Alexander Fleck on August 29, during the reception for exhibitioners in the Randolph Hall of the University of Glasgow. The competition is sponsored annually by Imperial Chemical Industries Limited, publishers of the quarterly scientific review *Endeavour*, and is limited to those under twenty-five years of age. Ninety-two entries were received, but, although many were from abroad, all the prize-winners this year come from the British Isles. The first prize of 50 guineas was awarded to Mr. Charles Perrin, of Winchester College, for an essay on "Darwinism Today". The second prize of 25 guineas was awarded to Miss Angela Glynn for an essay on "Education for an Age of Science". Miss Glynn is a student at Newnham College, Cambridge. The third prize of 15 guineas was awarded to Mr. John Christopher Horrocks, of Halifax, Yorkshire, for an essay on "Rockets and Satellites and their Scientific Significance". Mr. Horrocks is studying for an external London degree at Bradford Institute of Technology. Two special prizes of 5 guineas were awarded to competitors under eighteen. Mr. Anthony Orchard, of Swansea, received one of these for an essay on "Chemicals from Petroleum". He is at present at the Bishop Gore Grammar School for Boys. The second was won by Mr. Andrew Billson, of Nottingham, for an essay on the same subject. Mr. Billson is at the Becket School, West Bridgford.

NEWS and VIEWS

Physics at the University College of Wales, Aberystwyth : Prof. W. J. G. Beynon

Dr. W. J. G. Beynon, at present a senior lecturer in the University College of Swansea, has been appointed to the chair of physics at the University College of Wales, Aberystwyth, in succession to the late Prof. R. M. Davies (see *Nature*, 181, 879 ; 1958). Dr. Beynon graduated in the University of Wales (University College of Swansea) in 1934, with first-class honours in physics, and then proceeded to research in the Department of Physics at Swansea, obtaining his Ph.D. degree for work on magneto-optical dispersion in 1939. During 1938–46 he worked in the Radio Division of the National Physical Laboratory on ionospheric problems in radio communication. In 1946 he returned to the Department of Physics at Swansea as lecturer, being promoted to senior lecturer in 1949. With research students, he continued work on ionospheric problems, and in 1951 was awarded the degree of D.Sc. (Wales). His published work is concerned with radio-wave propagation, reflexion and absorption in the ionosphere, and in some papers he collaborated with Sir Edward Appleton. Recent publications have been on solar eclipses and radio studies during the International Geophysical Year, for which he is a 'world correspondent' on the ionosphere. He has been general editor of the Proceedings of the International Joint Commission on the Ionosphere, and has served on many committees, national and international, including those dealing with artificial Earth satellites, and rocket investigation of the upper atmosphere. He was a member of the official British delegation to General Assemblies of the Scientific Radio Union at Zurich (1950), Sydney (1952), The Hague (1954), and Boulder (1957), and has recently visited Moscow.

Report on Education

The report of the Ministry of Education, "Education in 1957" (pp. v+198. (Cmnd. 454). London: H.M. Stationery Office, 1958. 9*s*. net), brings together a good deal of information which has been given piecemeal to Parliament, and presents a convenient picture of trends, some of which, notably in further education, are of particular interest to the scientist. During 1956 the number of senior children in all-age schools was reduced by 10 per cent, while during 1957 completion of new buildings permitted the re-organization of 203 all-age schools, and there are 260 projects in the approved building programme, completion of which will enable 1,300 more all-age schools to be re-organized. New building work to the value of more than £60 million has now been authorized for the first four years of the five-year plan for the expansion of technical education, out of a total of £70 million, and by the end of 1957 work had begun on twenty new colleges and 102 major extensions to existing colleges. Although the staffing position in the primary schools improved slightly, it continued to deteriorate in the secondary schools, and the report emphasizes the need for a considerably larger number of teachers of mathematics and science when the number of children in the secondary schools rises in the next few years. Statistics and a graph included in the report point to a new peak expected in the school population in 1968 almost as high as that expected in 1961. The number of full-time teachers in technical colleges rose from 10,817 to 12,139, and of part-time teachers from 47,024 to 49,320, but the increase is still short of that considered necessary by the Willis Jackson Committee. The year was notable for the number of visitors to the Science Museum, the figure of 1,317,000 having only been exceeded in 1935 (1,327,000).

Russian Scientific Journals available in English

The U.S. National Science Foundation has published a useful list of Soviet scientific and technical journals now available in English translation. 60,000 pages a year are now in print and these include 53 English editions of Russian journals, four extensive series of translated Russian abstracts of scientific papers, and four series of partial translations of important Russian journals. The list includes subscription rates and details of where the translations can be ordered. It can be obtained from the National Science Foundation, Washington 25, D.C.

The Australian Museum, Sydney

So long ago as 1827 Earl Bathurst suggested that a public museum be established in New South Wales, where "many rare and curious specimens of natural history are to be procured". By 1852 the first portion of the permanent building had been erected. The whole building will be completed by the construction of the North Wing, which is due to begin very soon. From its early days, the Museum has been distinguished for arranging its exhibits in attractive form and for publications designed to appeal to all with an interest in natural history. The latest publication, "Handbook to the Australian Museum", replaces the former "Guide" and has been designed to help make visits to the Museum of increased interest by providing information not only about the exhibits themselves but also of the theme that links them all together. Approximately 250,000 people visit the Museum each year.

The report of the Trustees of the Australian Museum for the year ended June 30, 1957 (pp. 23. Sydney: The Australian Museum, 1958), includes a valuable summary of the growth and development of this progressive institution. The main purpose of this statement is to indicate that for a period of no less than forty-seven years no major building developments have taken place, and this in spite of many applications to the authorities for increased accommodation. Plans and designs for new displays have been prepared for the aboriginal, bird, fish, invertebrate, insect, mineral, mammal and fossil galleries. Special quarterly exhibits help to produce a lively atmosphere, and popular lectures on scientific subjects connected with the museum objects are well attended.

Library Resources in the West Midlands

The West Midlands Group of the Reference and Special Libraries Section of the Library Association has compiled a "Guide to Library Resources in the West Midlands" (pp. viii+49. London: Library Association, 1958. 15*s*.). Edited by B. G. Staples, it indicates the character, coverage and availability of 178 libraries in Herefordshire, Shropshire, Staffordshire, Warwickshire and Worcestershire. The staff, book-stock and number of periodicals, but not the titles, are given and only to a limited extent does it supply a picture of the resources of the region. There are two indexes: one, topographical, showing the different types of library in each locality; while the general index gives a key to particular subject fields and named collections, as well as indicating where microcard and microfilm readers and certain classes of material can be found. This well-produced pamphlet bears further witness to the preparatory work which this and similar groups are carrying out in different parts of Britain and on which an adequate regional library system may perhaps ultimately be based.

Health Physics

A new journal is a mixed blessing. The hopeful scribe sees in it another vehicle for his works, while the harassed executive sighs at the thought of more to read. Nevertheless, no one can grudge a new discipline its own organ. Health physics is such a new discipline; a Health Physics Society has recently been formed in the United States and has now published the first issue of its journal, *Health Physics* (1, No. 1, June 1958. Pp. 95. Subscription: 17 dollars; 120*s*. per annum. New York and London: Pergamon Press, 1958). In the foreword by K. Z. Morgan (editor-in-chief) health physics is defined "as a study and practice dealing with any and all factors relating to damage from ionizing radiation and the prevention of such damage". With the rapid promotion of nuclear energy and the increasing utilization of its by-products, there can be no doubt that the fantastic growth of this new corps of specialists from a handful of dedicated enthusiasts to a substantial army will be continued. They will welcome this journal devoted to "(1) Research, (2) Engineering, (3) Applied, and (4) General"—which is a fairly broad programme—and the first number, of June, has plenty of category (4).

"Atom 1959"

Under the title "Atom 1958" (pp. 24. London: H.M. Stationery Office, 1958), the Atomic Energy Authority has issued for general reading a summary, with illustrations, of the Authority's fourth annual report (see also p. 615 of this issue of *Nature*). The pamphlet describes in non-technical terms the progress of the power programme, the possibilities for the next two decades, including the prospects for a fusion reactor, and the relations of the Authority with industry and with other countries. Besides some notes on health and safety and the supply of fuel for reactors, it includes an outline of the Authority's organization and lists of its establishments and publications. It is a well-planned contribution to public relations which should help to remove some popular misunderstandings and dispel the dangerous sense of mystery with which those relations are sometimes cloaked.

Czechoslovak–Hungarian Polarographic Conference

The Czechoslovak–Hungarian Polarographic Conference in Prague was held during July 13–24 following the similar meeting held in 1955 at the Hungarian Chemical University in Veszprém. The Conference was arranged by the Polarographic Institute of the Czechoslovak Academy of Sciences under the auspices of its Chemical Section. Prof. J. Heyrovský presided. The Hungarian delegation consisted of nineteen scientists and was led by Prof. J. Proszt (Budapest Technical University), Prof. K. Polinszky (dean, Veszprém Chemical University) and Dr. V. Cieleszky (chairman, Polarographic Section, Hungarian Chemical Society). Besides these, there were thirty-five visitors from Budapest and several polarographic experts from other countries, including Prof. G. Semerano (Padua); Dr. Z. Zagórski (Poznań); W. Stolle (German Academy, Berlin), who brought a gift of a newly constructed pen-recording polarograph; L. Lukashev (Bulgaria); Prof. B. P. Bruns (Moscow); and Dr. R. J. Magee (The Queen's University, Belfast). Sixty-three papers were presented at the Conference in two sections: *A*, inorganic–analytical; and *B*, organic and biochemical. After the meetings in Prague the delegates went to Bratislava and were shown around research establishments and chemical works in Czechoslovakia, as well as the Tatra Mountains. The majority of the papers were of high standard and some indicated new directions in polarography. They will be published chiefly in "Collection of Czechoslovak Chemical Communications". Those who are interested in the abstracts of the Communications should apply to Prof. J. Heyrovský, Polarographic Institute of the Czechoslovak Academy of Sciences, Vlašská 9, Prague 1, Czechoslovakia.

A Submarine Volcano

As reported by Y. Y. Gakkel (*Priroda*, 4, 87; 1958), the members of the polar drifting station in November 1955 discovered a submarine volcano situated at 88° 16′ N., 65° 36′ W. on the Lomonosov submarine ridge near the North Pole. The nature of the ice-quakes, noises and hydrogen sulphide emerging from a crack in the ice—all these phenomena have suggested the presence of a submarine volcano in eruption. The author of this article postulates a tectonic fracture stretching along an arc from the Ellersmere Land to the Taimyr peninsula. Along this line the following newly discovered features can be located: the problematic volcano, dredged volcanic glass and basaltic hornblende, the latter being also found in other localities of the Arctic Ocean.

Seed Transmission of Plant Virus Diseases

OF the considerable number of known plant virus diseases, only some forty-five are reported to be seed-transmitted, and of these only a few cases of actual embryo infection are known. N. C. Crowley, who has already demonstrated the presence of virus inhibitors in the seeds of several species, but not of virus inactivators, has now made further contributions on this topic (*Austral. J. Biol. Sci.*, 10, 443 and 449; 1957). He has shown, by growing tomato embryos in media containing the virus, that there is no evidence for the presence of virus-inactivating substances in the embryos. Evidence is presented that whereas some of the highly infectious viruses commonly infect the seed testa, and even the endosperm, the developing embryo usually, and typically, remains uninfected. Since it has not been possible to obtain evidence of the presence of virus-inactivating agents in either the endosperm or the embryo, the favoured hypothesis to account for the rarity of seed-transmission is that the absence of plasmodesmatal connexions between the embryo and its tissue environment prevents its becoming infected. In a series of critical experiments, using well-known viruses and hosts, Crowley has shown to what extent the testa, the endosperm and the embryo may become infected in different cases. Again, all the evidence obtained indicates that the absence of seed-transmission of highly infectious viruses cannot be explained except in terms of the plasmodesmatal hypothesis. The alternative hypotheses (1) that the viruses induce sterility, (2) that the hosts contain inactivating substances, and (3) that developing embryos inactivate virus particles in the surrounding medium, are not validated by any evidence so far obtained. In the case of those virus diseases, for example, bean mosaic virus, that are seed-transmitted, this appears to depend on the ability of the virus to infect the microspores, macrospores or embryo sac before fertilization; but embryos themselves seem to be singularly free from infection. As the author points out, since natural selection would tend to eliminate any line of plants readily subject to the seed-transmission of a severe virus disease, the rarity of the latter phenomenon finds a simple and direct explanation.

Medical Research Council Travelling Awards

THE Medical Research Council has made the following travelling awards for the academic year 1958–59. *Rockefeller Travelling Fellowships in Medicine:* Dr. G. Burnstock, Department of Pharmacology, Oxford; Mr. P. J. Holloway, Medical Research Council Laboratories, Hampstead; Mr. W. B. Jennett, lecturer in neurosurgery, University of Manchester; Dr. A. P. Mathias, lecturer in biochemistry, University College, London; Dr. R. P. Michael, Department of Experimental Neuroendocrinology, Institute of Psychiatry, Maudsley Hospital, London; Dr. P. H. A. Sneath, National Institute for Medical Research, Mill Hill. *Lederle Travelling Fellowship in Medicine:* Dr. R. J. Linden, lecturer in physiology, University of Leeds. *Alexander Pigott Wernher Memorial Travelling Fellowship in Ophthalmology and Otology:* Dr. G. B. Arden, Institute of Ophthalmology, London. *French Exchange Scholarships in Medical Science:* Miss J. E. Cremer, Medical Research Council Toxicology Research Unit, Carshalton, Surrey; Miss S. Reiman, Institute of Psychiatry, Maudsley Hospital, London.

Travelling Fellowships in Medicine have been awarded by the Eli Lilly Company of Indianapolis, after nomination by the Medical Research Council, to the following candidates: Mr. J. D. Griffiths, St. Bartholomew's Hospital, London; Dr. C. W. M. Wilson, lecturer in pharmacology and therapeutics, University of Liverpool. Travelling Fellowships in Medical Science have also been awarded by the United States Public Health Services, National Institutes of Health, Bethesda, Maryland, after nomination by the Medical Research Council, to the following candidates: Dr. B. S. Hartley, Department of Biochemistry, University of Cambridge; Dr. K. W. Cross, St. Mary's Hospital Medical School, London; Dr. A. Doig, Royal Infirmary, Edinburgh.

Announcements

THE Ministry of Supply announces that Dr. J. S. McPetrie has been appointed director-general of Electronics Research and Development in succession to Dr. D. H. Black.

A MEETING of the Photobiology Group on "Some Aspects of the Physiology of Vision" is to be held in the University Laboratory of Physiology, Oxford, during September 26–27. Registration forms and further details can be obtained from the chairman of the Photobiology Group, Dr. M. H. Pirenne, University Laboratory of Physiology, Oxford.

THE Radio Frequency Spectroscopy Group (chairman, Prof. E. R. Andrew, Bangor) is to hold a conference on "Applications of Magnetic Resonance to Solid State Physics" at King's College, Newcastle upon Tyne (University of Durham), during September 22–23. The programme includes contributions on electron resonance of colour centres and iron group impurities in ionic crystals, nuclear resonance in ionic solids, electron spin, nuclear and cyclotron resonance in semi-conductors. Further particulars and application forms can be obtained from Dr. E. E. Schneider, King's College, Newcastle upon Tyne.

AN international conference on "Small Angle X-ray Scattering from Metals" will be held at Midwest Research Institute, Kansas City, Missouri, during September 23–25. The purpose of the meeting is to bring together active workers in the field to discuss the origin of the scattering as it relates to the crystal structure of metals. Arrangements for the conference have been made by the following committee: C. S. Barrett, Institute for Study of Metals, University of Chicago; Paul A. Beck, University of Illinois; W. W. Beeman, University of Wisconsin; and J. C. Grosskreutz (chairman), Midwest Research Institute, Kansas City, Missouri, from whom further information can be obtained. Financial support is being provided by the National Science Foundation, the Office of Ordnance Research, the Office of Naval Research, the Wright Air Development Center, U.S. Air Force, and Midwest Research Institute. The proceedings will be published as a special section of the *Journal of Applied Physics.*

THE ACCIDENT AT WINDSCALE ON OCTOBER 10, 1957

THE final report* on the accident to No. 1 pile at Windscale on October 10, 1957, should be considered in relation to the previous reports[1-3].

During a routine Wigner energy release, temperatures in the pile rose beyond safe limits, causing a fire which affected 150 channels and caused a certain amount of radioactivity, mainly iodine, to be released over an area of Cumberland. Following this incident, a committee of inquiry was set up under Sir William Penney, and reporting to the Prime Minister. A less technical version of its report has already been published[1]. In the memorandum by the Prime Minister the immediate cause of the accident was given as "the application too soon and at too rapid a rate of a second nuclear heating to release the Wigner energy from the graphite . . .". The accident was considered as being due partly to inadequacies in the instrumentation and partly to faults of judgment by the operating staff, these faults of judgment being themselves attributed to weaknesses of organization.

Three committees were set up, each under the chairmanship of Sir Alexander Fleck, to advise on certain aspects of the incident. The committees on Organization and on Health and Safety reported in December 1957[2] and January 1958[3], respectively. The report of the Technical Evaluation Committee, the subject of this article, was delayed due to the need to carry out a considerable amount of experimental and analytical work.

The Committee's terms of reference were: (1) to consider the new information available following the accident; (2) to consider the possible methods of carrying out the controlled release of Wigner energy; and (3) to advise the United Kingdom Atomic Energy Authority on the restarting of Windscale No. 2 pile.

The report begins by considering the phenomenon of energy storage in irradiated graphite—Wigner energy. This storage is due to defects in the crystal structure of the graphite following neutron bombardment. The energy is releasable, in varying extent and rate, by heating the graphite. The amount of energy stored decreases rapidly with an increase in the temperature at which irradiation takes place, that is, there is an annealing effect. This feature makes the effect particularly severe in low-temperature reactors such as BEPO and the Windscale piles, but very much less important in the Calder and subsequent power-producing reactors. The Committee states that if the release of energy in No. 2 pile was attempted as previously, graphite temperatures in excess of 400° C. would almost certainly occur in considerable masses of graphite, and that temperatures in some pockets where previous releases had not been effective might reach 500° C.

The report next considers the implications of these transient high temperatures on the graphite, the fuel and the other materials in the reactor. A temperature limit of 400° C. is considered as reasonable for the graphite. Under these conditions the fuel element design is satisfactory. Having specified temperature limitations, the real problem is that of installing sufficient and effective instrumentation. A considerable increase in the number of graphite and fuel element thermocouples is required, and the fission product detection scanning gear needs improving.

A description of four methods of carrying out Wigner releases is then given. The first method, the one previously employed, uses nuclear heating to initiate the release of energy. The main difficulty is the non-uniformity in the spread of the release, leaving pockets unannealed. The Committee deprecates the application of a second nuclear heating to initiate the release of these pockets, as being certain to lead to excessive uranium temperatures, and recommends that no further releases by this method should be attempted. The second method was used with the BEPO reactor in March this year, but is not recommended for Windscale. The third method, a slow heating method, is also discarded, since it would cause excessive stresses in the concrete reactor structure. The fourth method combines the previous two. It is proposed that a partial anneal using a slow heating method should first be carried out, followed by a more rapid heating to a somewhat higher temperature. The heat would be supplied by heating the ingoing air. The necessary plant and instrumentation could be installed in 6–9 months, making the pile operational again in about a year.

No. 1 pile has added considerably to our knowledge of reactor technology and operation. It is hoped that No. 2 pile will be recommissioned, since the development of methods for altering the pattern of the instrumentation in a reactor after it has been in service will prove most useful as the nuclear power programme develops.

EXCHANGE OF INFORMATION ON ATOMIC ENERGY

THE Agreement between the Governments of the United Kingdom and of the United States for Co-operation on the Uses of Atomic Energy for Mutual Defence Purposes described in the White Paper* published on July 8 comprises twelve articles. The first is a general provision for the exchange of information and transfer of materials and equipment, unless such co-operation represents an unreasonable risk to the defence and security of the communicating or transferring party. Under the second article the two parties agree to communicate or exchange classified information jointly determined as necessary to the development of defence plans, the training of personnel in the use of or in defence against nuclear weapons, the development of delivery systems for such weapons, and on research, development and design of military reactors, as well as other classified information required to improve the design, development and manufacture of nuclear weapons. The transfer of submarine nuclear propulsion plant and materials is covered specifically in the fourth article, while questions of responsibility, conditions and guarantees are dealt within the next three. Article VII restricts the communication of classified information or material transferred under the Agreement to third parties without prior authorization, and under Article VIII agreed classification policies are to be maintained and the present practice of consultation continued. The longest article (IX) is that dealing with patents, and includes provision for the issue of appropriate secrecy or prohibition orders. These clauses, however, make it possible for firms in one country to enter directly into relations with firms in the other on the sale of patents and licences, and should thus ease the exchange of information between the two countries where it had been hindered because information which was the property of individual British firms would, if exchanged, become the property of their American competitors.

Pp. 8. (Cmnd. 470.) (London: H.M. Stationery Office, 1958.) 6*d*. net.

As the Prime Minister explained in the House of Commons on July 8, the new Agreement, which supersedes that of June 1955, has been negotiated in consequence of the amendment of the United States Atomic Energy Act, 1954, so as to permit closer and more fruitful collaboration between Great Britain, the United States and other friendly countries. The Agreement was signed on July 3 but cannot become effective until it has lain before Congress for thirty sitting days, and the Prime Minister preferred not to comment at that time on the practical results which might be expected when the Agreement comes into effect. We had been in close touch with the Commonwealth countries during the negotiations leading to the Agreement and co-operation with these countries was covered by Article VII. On July 15 Mr. Macmillan added that the United States Atomic Energy Act, as amended, still did not permit the transfer of complete nuclear weapons or manufactured nuclear components of such weapons, and the Agreement accordingly dealt rather with research and development than with the actual interchange of weapons. Replying to further questions in written answers on July 17, Mr. R. A. Butler said that no commitments or understandings were entered into which might have the effect of surrendering patent rights in the Calder Hall type of reactor. British interests were satisfactorily safeguarded by the clauses of the Agreement, and the Government saw no reason to expect that the undertakings to make available to the United States Atomic Energy Commission information about the Calder Hall design and the standard fuel elements used in the Calder Hall reactors would have any substantial effect on our export prospects. In the House of Lords on July 21, the Earl of Gosford said that this information related only to the Authority's own dual-purpose reactors and did not and would not include information developed from Calder Hall and included by industry in its latest nuclear power station designs. The Agreement was concerned exclusively with co-operation in the use of nuclear energy for defence and not with arrangements for co-operation on civil uses.

COLONIAL DEVELOPMENT

THE schemes made under the Colonial Development and Welfare Acts in the period April 1, 1957–March 31, 1958, which are detailed in the latest return*, bring the total commitments, from April 1, 1946, under the Acts to £194,259,668, of which £17,203,311 is for research schemes. The totals for the year in question are £17,480,563 for development and welfare and £1,123,850 for research schemes. Of this last, £351,709 is for agriculture, £158,830 for tsetse and trypanosomiasis, £106,207 for medicine, £101,108 for insecticides, £76,859 for fisheries, £72,622 for social science, £52,240 for products research, £23,546 for locust control, and £14,340 for economic research.

Of the actual research schemes, £135,730 is supplementary provision for the East African Trypanosomiasis Research Organization, 1957–60; £70,156 for the Colonial Pesticides Research Unit, Arusha, 1957–58; £66,858 for maintenance of the Colonial Road Research Section at the Road Research Laboratory, Harmondsworth; £65,000 for expansion of vaccine production and associated research in Nigeria; £51,675 for agricultural research in Swaziland; a further £49,300 for expansion of the Tropical Products Institute; £49,064 for the East African Scientific and Industrial Research Organization, 1957–60; a supplementary £43,056 for the Colonial Microbiological Research Institute, Trinidad; £37,785 for soil and land use surveys in British Guiana; £34,185 to establish a Veterinary Investigational Laboratory in Bechuanaland; £32,992 for the Nigerian Institute of Social and Economic Research; and £30,938 for the joint capital housing programme for the East African Agricultural and Forestry Research and Veterinary Research Organizations.

Other major research schemes include £23,546 for the Desert Locust Survey; a supplementary £30,800 to establish a Soils Laboratory in Sarawak; £23,023 for the study of soil fertility maintenance in high-rainfall areas in Nigeria; a further £22,084 for the Fisheries Development and Research Station, Sierra Leone; a further £20,100 for the West African Institute for Trypanosomiasis Research; £19,370 for control of malaria in a hyperendemic area of East Africa; and a supplementary £15,833 for sugar technology research at the College of Tropical Agriculture, Trinidad.

The development and welfare schemes follow the general pattern of recent years. A further grant of £644,000 goes to the Central Organization for Overseas Geodetic and Topographical Survey; Kenya receives £507,880 for the intensification of African agricultural development, with a further £508,120 for Agricultural Department expenditure in connexion with that intensification. Farm development in Jamaica receives a further £750,880, with £177,375 for expansion of cocoa production. £156,973 goes for soil conservation in Basutoland; a further £81,394 for control of tsetse fly in the Bechuanaland Protectorate; and £234,000 for development of broadcasting services in Kenya. Among the many grants for road development may be mentioned £771,680 to the Western Region of Nigeria; £288,000 to Tanganyika (a further £280,000 for improvements to the Eastern Trunk Road); £300,000 for improvement of territorial roads in Kenya; £156,000 for survey of roads in Swaziland; £817,250 for construction of a trunk road from Scrian to Simanggang, Sarawak; and £103,692 for reconstruction of the East Coast Georgetown–Rosignol road, British Guiana. Grants of £464,295 to the Western Region, Nigeria, and £99,000 for the Scaries area, Sierra Leone, illustrate the grants for the development of water supplies. £200,000 is for the establishment of the Jamaica Institute of Technology, and among the many grants for university education can only be mentioned £198,000 for the erection of a Men's Hall of Residence at the University College of East Africa and a supplementary £154,650 for the erection of the new library; £200,000 towards a new library at the University of Hong Kong; and £156,188 for the construction of buildings for the Faculty of Medicine, University College of the West Indies. There are numerous grants for secondary and primary education, the largest being £584,000 for the expansion of general education in Lagos.

SAFETY IN MINES IN GREAT BRITAIN

THE Mines Inspectorate, apart from the Headquarters organization at London, is divided into eight divisions, namely, Scottish, Northumberland and Cumberland, Durham, North Eastern, North Western, East Midland, West Midland and Southern, and South Western. Each division is in the charge of a divisional inspector who is required, under the Coal Mines Act of 1911, to present an annual report to the Minister of Power. The reports* for each of the eight divisions for 1956 have been published at intervals during the first few months of 1958; these are the last reports under the 1911 Act, for the Mines and Quarries Act, 1954, became effective on January 1, 1957.

The reports follow a similar pattern, beginning with an introduction which contains short accounts of production in the divisions, reorganization of collieries, new work, introduction of new methods of working, new machines used and experimental work on techniques of mining, roof support, shot firing, ventilation and so forth. This is followed by a section devoted to administration, in which are summarized the establishment and organization of the staff, the activities of the inspectors, inspections made on behalf of workmen, and prosecutions. One of the most interesting and significant features of this section in the reports is that nearly every divisional inspector refers to a serious shortage of staff, although one or two gave their opinion that there were signs of improvement in the near future. The shortage of inspectors has meant that the amount of preventive work undertaken was much less than desirable. The effect of the shortage was aggravated by the additional work caused in preparation for the implementation of the 1954 Act at the beginning of 1957; for example, in one division alone the Divisional Committee of the Mining Qualifications Board (a committee which includes inspectors of mines) examined the qualifications of more than 2,000 mechanics and examined about 100 of these orally; and certificates were issued in that division for more than 500 deputies and for nearly 900 shot-firers.

Over Great Britain as a whole, proceedings were taken against two management officials. Managements took legal proceedings against subordinate officials and workmen in about 340 cases, more than half of which were for contraventions in connexion with contraband (matches and smoking); two-thirds of these cases occurred in one division.

The main section of each report deals with accidents and their prevention. During the year there were 300 fatal accidents at mines (compared with an average of 396 in the three preceding years), and more than 1,760 men reportably injured (about 1,900 on the average in the three preceding years). There were also 148 dangerous occurrences (gas ignitions, fires, breakages of winding gear and so forth). Accidents are investigated and analysed by the inspectors. There is, considering the country as a whole, a gradual downward trend in the number of fatalities and reportable injuries each year, and in two divisions they were the lowest ever recorded; the numbers are, as the inspectors stress, unduly high. An analysis of all the accidents in 1956 shows that, in the opinion of the examining inspectors, about 80 per cent were avoidable (the actual percentages in different divisions vary from 76·3 to 81·7) and the remaining 20 per cent "unavoidable under existing conditions".

Of the avoidable accidents, some were due to defective machinery, some to neglect or breach of rules by officials or by workmen, but most (from about a half to three-quarters of avoidable accidents in different divisions) were classified as "avoidable by ordinary caution". Over Great Britain as a whole, about 35 per cent of the accidents were due to falls of ground, about 25 per cent were on haulage and transport, about 30 per cent due to miscellaneous causes, and about 10 per cent were due to accidents on the surface.

Sections in each of the reports are devoted to safety organization, training and education, and health and welfare. A noteworthy feature is the interest taken by miners in rescue training and rescue competitions, in first-aid work and competitions and in civil defence work. The rescue organization of the coal mining industry, which depends largely upon rescue teams of volunteers trained at special rescue stations, is a fine one and, as reported by the inspectors, whose duties include inspection of the rescue stations, there is no lack of volunteers for rescue work.

* Ministry of Power. Reports of H.M. Inspectors of Mines under the Coal Mines Act 1911, for 1956. Durham Division. By W. Brown. Pp. ii+30+8 plates. 2*s*. 6*d*. net. North Western Division. By G. Hoyle. Pp. ii+36+4 plates. 3*s*. net. North Eastern Division. By C. W. Scott. Pp. ii+38+6 plates. 2*s*. 6*d*. net. Scottish Division. By W. Widdas. Pp. ii+28+4 plates. 2*s*. 6*d*. net. East Midland Division. By W. B. Brown. Pp. ii+34+4 plates. 3*s*. net. South Western Division. By T. A. Jones. Pp. ii+24+4 plates. 2*s*. 6*d*. net. West Midland and Southern Division. By J. E. Henshaw. Pp. ii+24+2 plates. 2*s*. 6*d*. net. Northumberland and Cumberland Division. By H. Hyde. Pp. ii+30+6 plates. 2*s*. 6*d*. net. (London: H.M. Stationery Office, 1958.)

The inspectors, as their reports show, take a keen interest in training and education, and report on the training centres, training faces and courses of instruction in each division. In 1956 more than 17,000 juveniles and more than 15,000 adults received preliminary training; these figures indicate the immense task of training in the coal industry, especially as face training has to be arranged and courses for potential shot-firers and potential deputies (quite apart from courses for senior officials, which are not referred to in detail).

Sections on health and welfare refer mainly to work carried out in improving dust control, ventilation, lighting, sanitation and so forth, and to the provision of medical centres at collieries.

Each divisional report includes a section devoted to horses. Although the number of horses employed at collieries is decreasing, more than 10,000 were employed in 1956. In general, the miner is devoted to his horses and they are well cared for.

Although the general pattern of the reports is similar, they are not stereotyped. Probably few people unconnected with the mining industry will read them, but they are very well worth reading, for they are personal reports and are far from the dry-as-dust documents they might have been.

The reports for 1957 of H.M. Inspectors of Mines and Quarries under the Mines and Quarries Act, 1954, have also recently been published; these are the first reports under the 1954 Act which became effective on January 1, 1957. It makes provision for all classes of mines and quarries to be dealt with together, and the Inspectors' reports include, in separate parts or sections, reports on coal mines; mines of stratified ironstone, shale and fireclay; miscellaneous mines (including metalliferous mines); and quarries*.

The general pattern is similar to the earlier divisional reports, which dealt only with coal mines and other so-called stratified mines. As may well have been expected, by far the greater part of each report deals with coal mines and the conclusions are similar to those for 1956.

Until 1957 the reports of H.M. Inspectors of Mines and Quarries on metalliferous mines and quarries were presented in a single publication for the whole country by H.M. Chief Inspector of Mines and Quarries under the Metalliferous Mines Regulation Act, 1872, and the Quarries Act, 1894; the last report under these Acts was published early in 1958 and referred to the years 1954–56. The new arrangement under the 1954 Act whereby H.M. Inspectors report annually on all mines and quarries in their division is more convenient in many ways than the former biennial reports.

The new reports show that particular attention is being paid at quarries to dust prevention and dust suppression and to encouragement in the use of protective clothing, especially safety hats, which many quarrymen seem loath to wear.

PRESSURE WELDING OF METALS

Welding engineering is a profession now well established in industry and is supported by a research association and a technical institute. In Britain (unlike the United States and the U.S.S.R.) it has not achieved independent status at any university, and it is therefore practised by metallurgists and mechanical, electrical and civil engineers, in whose training it has occupied a very subsidiary role. However, as a result of the division of metallurgy into physical and industrial aspects at the University of Birmingham, research into and the teaching of the basis of metallic jointing practice now figures prominently in the Department of Industrial Metallurgy. To supplement the academic work, occasional conferences are organized to promote the exchange of information and ideas with other workers in the field. The second of these conferences, on the pressure welding of metals, was held on June 19, under the chairmanship of Prof. E. C. Rollason, head of the Department of Industrial Metallurgy, and was attended by ninety representatives of industry, the research associations and the universities.

After explaining the purpose of these conferences, Prof. Rollason reviewed the origins and development of the practice of pressure welding and the progress that had been made towards establishing a theoretical model. Three papers were then presented, the first by Mr. J. A. Donelan (Research Laboratories, General Electric Co.) dealt with industrial practice, the second by Messrs. L. R. Vaidyanath, M. G. Nicholas and D. R. Milner gave an account of the researches being carried out at the University of Birmingham, and the third paper by Dr. E. Holmes (University of Nottingham) was concerned with the relative importance of movement at the interface, oxide break-up, and the deformation of surface asperities upon bond formation.

The idea of joining metals by pressure is not new, as it has been employed in the hammer-forged blacksmith's weld from the earliest days of the use of iron; this, however, is a special case in that it depends on the squeezing out of a molten layer of slag between the two components to be joined. The general practice of pressure welding metals, without melting, was established in 1887 with resistance heating used to aid the deformation of the interface; then, during the Second World War, the cold welding process was developed in which metals are joined at room temperature. The majority of metals can now be pressure welded, if not at room temperature, then at higher temperatures. The advantages of the process are that the joint possesses none of the weaknesses inherent in the cast structure associated with the more normal welding techniques, and it is the only metallic jointing process that can be carried out at room temperature, and is therefore particularly suitable to the canning of delicate components such as detonators or transistors. One of the widest applications of pressure welding is to the production of ply metals by rolling, so that the advantages of the properties of two or more metals or alloys can be combined, for example, to provide corrosion resistance, as in the cladding of high-strength aluminium alloys with a thin layer of super-purity aluminium, or for economical reasons as in the cladding of mild steel with a thin layer of stainless steel.

Pressure welding practices developed empirically, and it was soon found that metals varied markedly in their welding characteristics, the criterion of weldability usually adopted being the amount by which two pieces of metal when placed together have to be deformed in order for them to join : thus, for example, at room temperature overlapped strips of tin and lead require a reduction in thickness of about 20 per cent, aluminium and copper 50 per cent, and nickel and iron 80 per cent. Cold welding is largely applied to aluminium and copper, and Mr. Donelan cited many applications in the electrical industry such as joining the ends of wires and rod, the formation of cable sheath from strip, and the fabrication of electric kettles and refrigerator coolant panels. Mr. Donelan stressed that for successful welding the most important factors are the surface preparation of the material (a degreasing treatment followed by scratch brushing being preferred), and the shape of the deforming tool.

The understanding of the phenomenon of pressure welding lags behind its practice and no satisfactory theory has been developed, although several hypotheses have been advanced as to the nature of the controlling parameter. When pressure welds could only be made at high temperatures it was considered that diffusion at the interface was essential to bring the surfaces into atomic contact, and for this reason that welding was enhanced at the recrystallization and transition temperatures, at which the rate of diffusion was considerably increased. With the advent of cold pressure welding emphasis was transferred from the influence of the temperature of welding to the pressure applied, which then came to be regarded by some workers as the controlling factor. These hypotheses, however, take little account of the practical necessity for careful surface preparation before welding, and more recent theories have concentrated on this aspect, in one case the penetration and fragmentation of the oxide film being regarded as critical, whereas in another case the difficulty of bringing roughened surfaces into intimate contact has been stressed. An alternative hypothesis has been advanced which implicitly assumes that the formation of bonds presents no difficulty, but that on release of the applied load these bonds are at least partially broken apart by elastic recovery forces which vary from one metal to another. Finally, there is the possibility of relative movement between the joining surfaces which, as workers in the field of friction have shown, leads to the formation of welds that are responsible for frictional restraint. None of the models suggested has been developed in detail and none of them can explain all the observed facts.

The difficulties in making an analysis of bond formation are : first, the large number of parameters involved ; and second, the fact that no satisfactory method has been developed for the measurement of the degree of bonding or weld strength which is obtained. Part of the theme of the work of Vaidyanath, Nicholas and Milner was that the mechanism of pressure welding is best investigated via the roll bonding process, since for practical purposes the reduction is uniform throughout the composite and it is possible to measure the bond strength by a test giving results which are more amenable to analysis than those available hitherto. This work has led to the development of a theoretical model for the maximum joint strength that can be obtained from the concept that oxide films are completely brittle, so that when the interface is extended, areas of virgin metal are exposed and these are the sources of potential bonding. However, the problem remains of why these virgin metal areas do not always join. From evidence on the effect of pressure, time, temperature, and exposure of the surface to the atmosphere prior to rolling, the authors concluded that a correct theory must involve considerations of atomic movements during deformation, diffusion and the solution of entrapped gases.

When dissimilar metals are welded, further problems arise in that if the two metals possess different mechanical properties they will not deform in the same manner and, in addition, alloy layers will develop at the interface and have a marked effect on the joint strength. Dr. Holmes showed that when dissimilar metals are bonded by rolling there will also be relative movement between the two surfaces as they enter the roll gap and that this could lead to substantial bonding without much deformation, the bond strength increasing with the amount of relative movement and with the applied load under which the movement was carried out. From further experiments, designed to examine the relative importance of the difficulty of bringing rough surfaces into intimate contact and that of penetrating the oxide film, Dr. Holmes reached the conclusion that for conditions under which the flow of metal was restrained oxide break-up was difficult to obtain, whereas, since restraint of necessity involves higher pressures, the deformation of asperities was readily achieved. Conversely, for conditions of low restraint, metal flow and oxide break-up took place readily and the deformation of the surface asperities became the controlling process.

The points raised during the discussion showed that pressure welding is contributing to the solution of some of the problems arising from modern technical developments, two examples of the use of cold welding being the joining of the trans-Atlantic cable and the fabrication of complex patterns of frozen mercury for precision casting. The disadvantage remains that in many cases considerable deformation is required, but a recent development has shown that this can be very much reduced by the application of ultrasonic vibration during the welding process. The use of impact loading was also discussed, but the results were inconclusive ; some indicated little difference, while others suggested considerable improvements, from the bond strengths obtained by deformation at conventional speeds. The divergence of the opinions expressed on the theory of pressure welding showed how little can be regarded as universally acceptable, and the ultimate answer will probably show that the controlling parameter varies with the conditions of welding. The technique of surface preparation prior to welding received considerable discussion, and it is found that the best welds are achieved with scratch-brushed surfaces : with many other surface treatments, or no surface preparation, it is often impossible to obtain any bonding. That no satisfactory explanation could be offered for the success of the scratch-brushing practice demonstrated again the inadequacy of the present state of the theoretical treatments of the subject.

D. R. Milner

USE OF ARTIFICIAL SATELLITES TO EXPLORE THE EARTH'S GRAVITATIONAL FIELD: RESULTS FROM *SPUTNIK* 2 (1957β)

By R. H. MERSON and D. G. KING-HELE
Royal Aircraft Establishment, Farnborough

IT is well known that the Earth's oblateness and its atmosphere cause the main perturbations to the orbit of a near Earth-satellite, and various theoretical studies of these effects have been made. Now that accurate observations of satellite orbits are available it becomes possible, at least in principle, to reverse this procedure and to use the theories to obtain a better knowledge of the atmosphere and the Earth's gravitational field. This article gives some tentative conclusions about the gravitational field, after a comparison of theory with observation for *Sputnik* 2 (1957β).

Fortunately, it happens that the first-order perturbations due to the atmosphere and the Earth's oblateness are of different kinds: the air drag steadily reduces the length of the major axis and the eccentricity of the orbit[1], while the Earth's oblateness causes the orbital plane to rotate about the Earth's axis and the major axis of the orbit to rotate in the orbital plane. The rotation of the major axis is difficult to determine; but, as Buchar[2] has remarked, the rotation of the orbital plane, which can be measured very accurately, should provide new information about the gravitational field.

The gravitational potential U due to the Earth at an exterior point distant r from the centre may be expressed in spherical harmonics $S_n(\theta,\varphi)$ as:

$$U = \sum_{n=0}^{\infty} A_n r^{-n-1} S_n(\theta,\varphi) \qquad (1)$$

where θ is the angle between the radius vector and the Earth's axis (the co-latitude), φ is the longitude and the A_n are constants. If the potential is assumed to be independent of longitude and the equatorial plane is suitably chosen, equation (1) may be written more explicitly as:

$$U = \frac{fM}{R}\left\{\frac{R}{r} - \sum_{n=2}^{\infty} J_n\left(\frac{R}{r}\right)^{n+1} P_n(\cos\theta)\right\} \qquad (2)$$

where f is the gravitational constant, M the mass of the Earth, and R the Earth's equatorial radius. P_n is the Legendre polynomial of order n and the J_n are constants. Of the coefficients J_n, only J_2 is at present known at all accurately, and it is customary to express U in the form recommended by Jeffreys[3] as:

$$U = \frac{fM}{R}\left\{\frac{R}{r} + J\left(\frac{R}{r}\right)^3\left(\frac{1}{3} - \cos^2\theta\right) + \frac{D}{35}\left(\frac{R}{r}\right)^5(35\cos^4\theta - 30\cos^2\theta + 3)\right\} \qquad (3)$$

where the coefficients J and D are related to the J_n of equation (2) by $J = \frac{3}{2}J_2$ and $D = -\frac{35}{8}J_4$.

The geopotential Ψ is obtained by adding a term $\frac{1}{2}w^2 r^2 \sin^2\theta$ to U, to allow for the angular velocity w of the Earth, and Jeffreys chose the coefficient D in (3) to make the value of Ψ constant over a spheroid of equatorial radius R and polar radius $R(1 - \varepsilon)$, which was taken as an approximation to the real Earth, with ε as the polar flattening. With these assumptions:

$$J = \varepsilon - \frac{m}{2} - \varepsilon\left(\frac{\varepsilon}{2} - \frac{m}{7}\right) + 0(\varepsilon^3) \qquad (4)$$

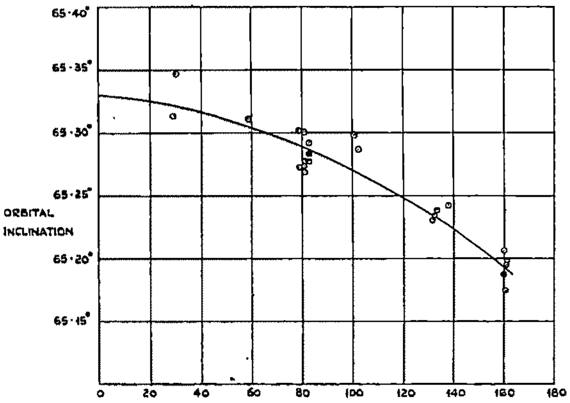
and

$$D = \frac{\varepsilon}{2}(7\varepsilon - 5m) + 0(\varepsilon^3) \qquad (5)$$

where $m = R^3w^2(1 - \varepsilon)/fM$ is the ratio of centrifugal to gravitational acceleration at the equator, multiplied by $(1 - \varepsilon)$. The value of m is accurately known ($10^6 m = 3449{\cdot}79 \pm 0{\cdot}06$), while from geodetic measurements Jeffreys deduced that $J = 0{\cdot}001637 \pm 0{\cdot}000004$, which gives $1/\varepsilon = 297{\cdot}1 \pm 0{\cdot}4$. Then from (5), $D = 10{\cdot}6 \times 10^{-6}$.

The mean rate of rotation of the orbital plane, $\dot{\Omega}$, for a near satellite in the gravitational field defined by (3) is found[4] to be:

$$\sqrt{\frac{fM}{a^3}}\left(\frac{R}{\bar{r}}\right)^2 \cos\alpha\left[J + J^2\left(\frac{R}{\bar{r}}\right)^2\left(\frac{19}{12}\sin^2\alpha - 1\right) - \frac{3DR^2}{14\bar{r}^2}(7\sin^2\alpha - 4) + 0(J^2e)\right] \qquad (6)$$



[*Crown copyright reserved*

Fig. 1. Mean orbital inclination of *Sputnik* 2 (1957β)

in the opposite direction to the satellite's motion, where a is the semi-major axis of the orbit, $\bar{r}$ the semi-latus rectum, e the orbital eccentricity and α the mean inclination of the orbital plane to the equator.

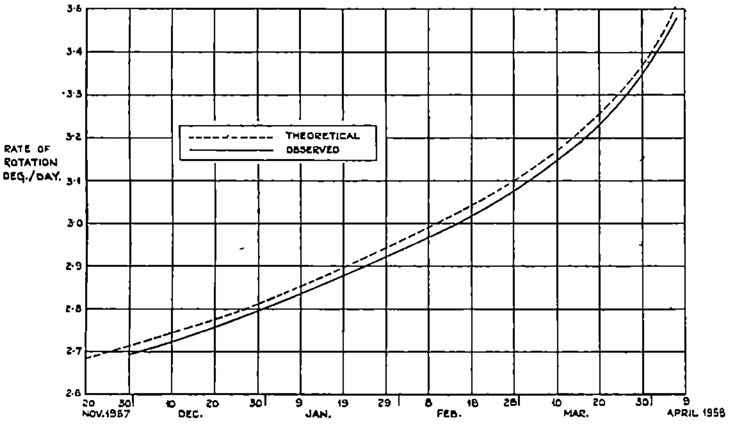
The expression (3) for U implies that the Earth is symmetrical about the equatorial plane. In considering the observational results, however, it is as well to remove this restrictive assumption and to include the third harmonic, a term:

$$\frac{fM}{R} J_3 \left(\frac{R}{r}\right)^4 \tfrac{1}{2}(5 \cos^3 \theta - 3 \cos \theta)$$

on the right-hand side of (3). It has been found (Merson, R. H., and Plimmer, R. N. A., unpublished work) that this gives rise to an extra term:

$$-\frac{3}{8}\sqrt{\frac{fM}{a^3}}\left(\frac{R}{\bar{r}}\right)^3 J_3\, e \sin \omega \cot \alpha \,(15 \sin^2 \alpha - 4) \quad (7)$$

in (6), where ω is the mean argument of perigee.



[*Crown copyright reserved*

Fig. 2. Rate of rotation of orbital plane of *Sputnik* 2

In the theoretical formula for $\dot{\Omega}$, as given by (6), the value of $\cos \alpha$ is much less accurately known than the other factors outside the square brackets, and in comparing the theoretical and observed values of $\dot{\Omega}$, it is this uncertainty in $\cos \alpha$ which sets the limit to the accuracy. The value of α for *Sputnik* 2 has been determined from a series of kinetheodolite observations made at Ministry of Supply stations at Aberporth, Bramshot, Larkhill, Orfordness and West Freugh. These have been analysed using a Pegasus digital computer at the Royal Aircraft Establishment (the method of analysis is described elsewhere[5,6]) and the results are plotted in Fig. 1. It is found that

$$\alpha = 65{\cdot}331° - 0{\cdot}00018°\, t - 0{\cdot}0000043°\, t^2 \pm 0{\cdot}02° \quad (8)$$

where t is the time in days after November 3·0, 1957.

This marked decrease in α, at the rate of about 0·001 deg./day, has not yet been satisfactorily explained. The theoretical formula for $\dot{\alpha}$ for an orbit *in vacuo* contains terms in J_3e, De^3 and J^2e. The value of $\dot{\alpha}$ given by this formula does not appear to be large enough to account for the observed change, however. Also, if the decrease were due to the J_3e term, the rate of decrease should tend to zero at the end of the life-time of the satellite when $e \to 0$, whereas Fig. 1 indicates that the decrease becomes sharper towards the end. This suggests that the change may be due to some second-order effect of the atmosphere, and possible causes, such as rotation of the atmosphere, are being investigated.

The theoretical value of $\dot{\Omega}$ during the life-time of *Sputnik* 2 has been calculated from the expression (6), using the values of J and D recommended by Jeffreys[3], values of α from (8), and values of other orbital elements derived from kinetheodolite observations and from theodolite observations made at Jokioinen, Finland. At the same time, observed values of Ω, the right ascension of the ascending node, have, after suitable curve-fitting, been differentiated and values of $\dot{\Omega}$ (observed) have been obtained. Fig. 2 shows the variation with time of the theoretical and observed values of $\dot{\Omega}$. It was found that the ratio $\dot{\Omega}$ (theoretical)/$\dot{\Omega}$ (observed) remained virtually constant during the life-time of *Sputnik* 2 and had the value 1·0068 ± 0·0003.

Since this ratio remained so nearly constant, it seems highly improbable that the discrepancy is due to atmospheric effects, which should increase steadily as time goes on. The effect of the J_3 term can also be discounted since the factor $e \sin \omega$ in (7) decreases markedly during the life-time of the satellite. A change in either J or D, however, would change $\dot{\Omega}$ by a nearly constant factor, because the ratio of the J-term to the D-term in (6) does not vary by more than 10 per cent during the life-time of the satellite. It therefore seems probable that one or both of the constants J and D is in need of revision.

The discrepancy between the observed and theoretical values of $\dot{\Omega}$ could be explained either by a change in J from 0·001637 to 0·001626 (corresponding to a change in $1/\varepsilon$ from 297·1 to 298·1 ± 0·1), or by a change in D from $10{\cdot}6 \times 10^{-6}$ to 45×10^{-6}. How the changes should be apportioned between J and D can best be decided by accurate observations on a satellite with different orbital inclination. The preliminary information so far available to us on the first of the three U.S. satellites, which had inclinations near 35°, suggests that the observed values of $\dot{\Omega}$ are, as for *Sputnik* 2, lower than the theoretical. Since the D term in (6) changes sign when α changes from 65° to 35°, it seems likely that the discrepancy is due mainly to the J-term and that J needs to be reduced, though not necessarily to the value given above.

We wish to thank the kinetheodolite observers of the Ministry of Supply, and Dr. G. Järnefelt, of the Jokioinen Meteorological Observatory, Finland, for providing the observations on which these results are based.

AND

G. V. F. SEAMAN
Department of Colloid Science, University of Cambridge

Introduction

THE most widely used apparatus for electrophoresis of small particles have employed either rectangular[1–4] or cylindrical[5–9] chambers. The former has gained more adherents recently because of the optical difficulties[10,11] associated with cylindrical designs. The apparatus now described has been developed especially for studying the surface properties of tissue cells where rapid measurement and accurate temperature control are required.

Three features of this apparatus distinguish it from others previously used: (1) The tube is fixed permanently in position and is washed out *in situ*. (2) A dial test indicator is incorporated, allowing the microscope to be rapidly focused at the correct level independent of any inaccuracies in the fine adjustment screw. (3) The objective and electrophoresis tube are immersed in water, which simplifies temperature control and reduces the refraction by the cylindrical lens of the capillary wall. A reading can be taken and the tube cleaned in five minutes. The readings are reproducible to within 3 per cent. The apparatus is simple, robust and easy to construct.

Theory of the Cylindrical Cell

There are two electrokinetic effects in a closed glass tube containing a suspension of particles in an applied electric field. There is motion of the particles with respect to their suspending medium (electrophoretic effect) and a movement of liquid relative to the wall of the capillary (electro-osmotic effect) with a return flow of liquid down the centre of the tube. This produces a parabolic distribution of particle velocities across the diameter of the tube. The mobility of particles is measured at the stationary level, the position of which is derived below.

Lamb[12] has shown that for the closed cylindrical tube:

$$V_w = \frac{P}{4\eta}\,(r^2 - \tfrac{1}{2}R^2) \tag{1}$$

where V_w is the velocity of the liquid, P the hydrostatic pressure gradient parallel to the axis, η the coefficient of bulk viscosity of the liquid, and r the distance from the axis of the tube of radius R. The velocity at the surface of the tube $V_s = PR^2/8\eta$; hence (1) may be written:

$$V_w = V_s\,(2r^2/R^2 - 1) \tag{2}$$

The observed velocity V_0 of a particle is equal to $V_e + V_w$, where V_e is the electrophoretic velocity, hence:

$$V_0 = V_e - V_s + V_s\,(2r^2/R^2) \tag{3}$$

so that the velocity of a droplet is a linear function of the square of its distance from the axis of the tube.

Now $V_w = 0$ when $2r^2 = R^2$ or $r = R/\sqrt{2}$ (stationary level condition). Hence $r = 0{\cdot}707R$ from the axis or $0{\cdot}293R$ from the wall of the tube.

To ensure that all readings are taken at the stationary level, either that level alone is illuminated or, as in the present equipment, the microscope is set so that only the particles at the stationary level are in focus.

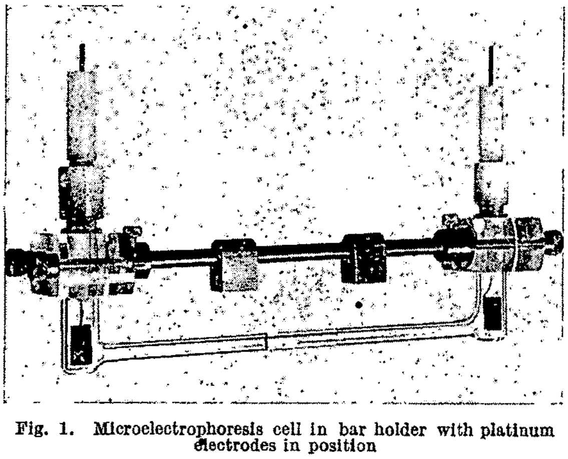

Fig. 1. Microelectrophoresis cell in bar holder with platinum electrodes in position

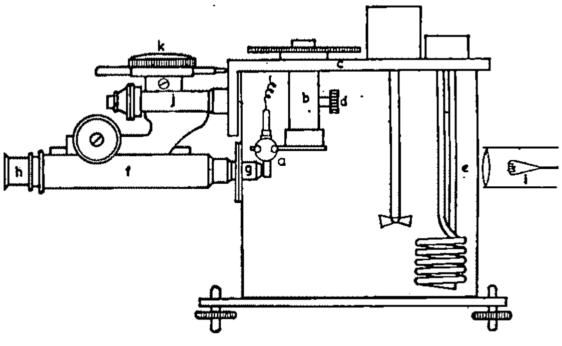

Fig. 2. Microelectrophoresis apparatus. *a*, tube holder; *b*, calibrated vertical traverse; *c*, crossbar; *d*, locking screw; *e*, thermostat; *f*, microscope tube; *g*, objective; *h*, micrometer eyepiece; *i*, light source; *j*, microscope fine adjustment; *k*, dial test indicator

Henry's correction[10] applied to the chamber of 'Veridia' glass (refractive index 1·47) amounts to 0·12 *R* when focusing is performed in air and is reduced to 0·01 *R* by immersing the objective in water.

Because of its rotational symmetry the mathematical expression of the velocity distribution for a cylindrical tube is more exact than that for the rectangular chamber where no theoretical correction for perturbation in the electro-osmotic flow produced by the side walls is made. In addition, symmetrical exchange of heat across the wall of the tube will tend to minimize convection currents.

The apparatus is illustrated in Figs. 1 and 2.

The Microelectrophoresis Tube

The tube consists of a cylindrical precision capillary of 'Veridia' glass; internal diameter uniform to ± 0·01 mm. The exact internal diameter chosen depends on the working distance of the objective; a diameter from 2·0 to 3·0 mm. is suitable for use with most × 40 objectives. At less than 1·5 mm. diameter the change in mobility of particles with depth in the tube is very large in the stationary level region, leading to large errors in mobility determinations for only small setting errors. Thermal convection effects are readily produced in tubes greater than 3·0 mm. in diameter because of the greater current flowing per unit field strength. A capillary tube of about 150 mm. was chosen since this length is convenient for levelling the cell accurately. There is no risk of contamination by electrode products since a current flowing for five times as long as is required for a mobility determination leads to contamination of approximately only the first 2·0 mm. of each end of the capillary.

'Quickfit and Quartz' *B*10 'Pyrex' sockets were fused to each end of the capillary tube and the viewing region formed by grinding and polishing a flat on the capillary wall. The capacity of the apparatus is approximately 5·0 ml. For the examination of very small quantities a similar tube fitted with *B*7 joints with a capacity less than 2·0 ml. is used. Electrodes of grey platinum[13] are inserted into the *B*10 'Pyrex' sockets. They consist of platinum foil of dimensions 12·5 × 20·0 mm., so that the current density is sufficiently low to obviate serious risk of polarization. The foil is formed into a cylinder and welded on to platinum wire which is inserted into a reservoir of mercury through a *B*10 soda glass or polyethylene plug. Reversible silver/silver chloride or copper/copper sulphate electrode systems were not used because of their greater complexity and the risk of contamination of the suspension with copper or silver salts. For currents less than 2·0 m.amp. reliable results can be obtained from these irreversible electrodes.

The Tube Holder

The tube is fixed horizontally in a holder (in Fig. 2,*a*) attached to a calibrated vertical traverse (*b*) (reading to 0·01 mm.) mounted on a crossbar (*c*) on the water-bath. A locking device (*d*) is incorporated in the adjustable traverse. Both tube and holder are immersed in a glass or 'Perspex' water-bath, the temperature controlled to ± 0·1° with an immersion heater (500 kW.) and a toluene regulator and 'Sunvic' switch or any other thermostatic device (*e*). The tube is set so that its capillary lies parallel to the surface of the water in the bath. Cleaning is effected *in situ* using a polyethylene cannula and a suction pump. When systems of low ionic strength are used, chromic acid cannot be employed with safety as a cleaning agent unless time is allowed to leach the adsorbed chromate ions from the glass wall of the cell. A molar solution of sodium chloride is used for rinsing out between determinations at low ionic strength ($< 0{\cdot}01$).

The Microscope

The microscope tube, 160 mm. long (Fig. 2,*f*), attached horizontally to the crossbar (*c*), is fitted with a × 40 $\frac{1}{8}$-in. waterproofed objective numerical aperture 0·7 (*g*), and a × 10 micrometer eyepiece (*h*) incorporating a chessboard graticule (5 × 5 squares of 0·25 mm. side). The optical system gives a magnification of 400 diameters and is calibrated against a 1·0 mm. standard micrometer scale divided to 0·01 mm. The depth of focus is about 0·005 mm.

A light source (*i*) is conveniently mounted behind the water-bath at right angles to the tube and co-axial with the objective. The objective is inserted into the bath through a water-tight rubber gasket and can be focused on the optical flat of the tube or on the stationary level using the horizontal fine adjustment of the microscope (*j*).

An adjustable zero dial test indicator (*k*) reading to 0·002 mm. is mechanically linked to the fine adjustment of the microscope (*j*) and bears on the crossbar (*c*) to give rapid and accurate reading of the objective setting.

The rate of movement of the particles is found by timing them (stop-watch reading 0·1 sec.) over a fixed number of graticule divisions selected so as to give a reading of about 10 sec. at an applied potential gradient of 3–5 V. cm.$^{-1}$. The direction of the current is reversed half-way through each reading to minimize polarization. A mobility value is normally based on determinations on ten individual particles and is expressed in μ sec.$^{-1}$ V.$^{-1}$ cm.$^{-1}$.

Circuit

This is shown in Fig. 3. A 150 V. radio battery supplies the potential through an on/off switch to the 25 *k* linear potentiometer (*P*1) which acts as a potential divider. (*V*) is a Braum 0–100 μamp. centre–zero micro-ammeter with a top grade 1·0 megohm resistor (*R*) and a 100 *k* linear carbon potentiometer (*P*2) in series to give a 0–200 V. direct-reading high-resistance voltmeter. (*A*) is a Pye 'Scalamp' (7901/5) shunted galvanometer, sensitivity 15·6 mm./μamp. on direct reading position. The two-way double pole switch (*D*) is wired for reversing the polarity of the electrophoresis cell, but not that of the meters in the circuit.

The potential gradient was obtained directly using the applied potential and the distance between the electrodes and indirectly using the relationship field strength $F = I/KA$, where A is the cross-sectional area, I is the current passing through the tube, and K the specific conductivity of the dispersion. The two methods were found to be in excellent agreement for the systems tested.

Experimental

Since the electrophoretic mobility for washed human and sheep erythrocytes (0·1 per cent v/v suspension) in 0·145 *M* sodium chloride with added 0·145 *M* hydrochloric acid or sodium hydroxide is

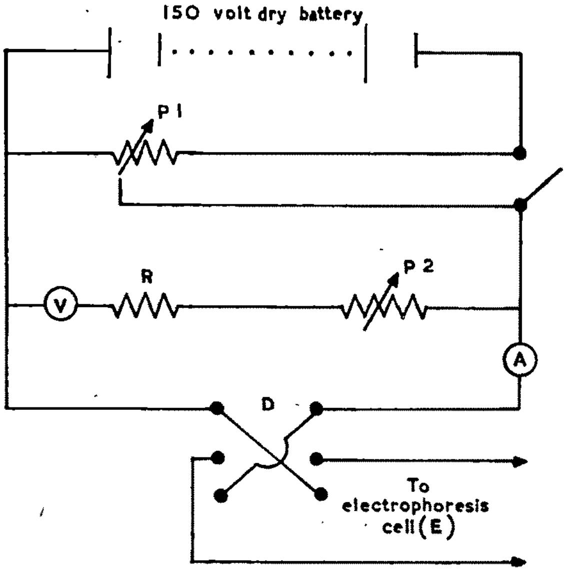

Fig. 3. Circuit diagram. *P*1, 25 *k* linear potentiometer; *P*2, 100 *k* linear potentiometer; *R*, 1 megohm resistor; *A*, galvanometer; *V*, centre-zero high-resistance voltmeter; *D*, reversing switch

constant over the *p*H range 5·0–9·0 [14], it is possible to locate the stationary level experimentally as the point of intersection of a series of *p*H depth-mobility curves (see Fig. 4). For the cylindrical tube it is also found that the relationship between velocity of the particle and the square of the displacement from the axis is linear, as predicted by equation 3 (see Fig. 5).

The stationary level is thus found by calculation and experiment and the mobility of human red cells in phosphate buffer *p*H 7·4 (2·0 ml. *M*/15 KH_2PO_4 + 8·0 ml. *M*/15 $Na_2HPO_4.12H_2O$) was 1·28 ± 0·03 μ sec.$^{-1}$ V.$^{-1}$ cm.$^{-1}$ and in 0·145 *M* sodium chloride solution it was 1·07 ± 0·02 μsec.$^{-1}$ V.$^{-1}$ cm.$^{-1}$. Table 1 shows a selection of the most reliable results obtained by other authors for the phosphate and chloride systems. Other observations in the literature do not deviate by more than about 5 per cent from those quoted, if those which can be traced to some error in technique are excluded. The difference between the chloride and phosphate values is attributed to greater anion absorption in the partially divalent phosphate case. The results under the above conditions are extremely reproducible and are independent of race, sex, age or blood group.

PERCHLORATE, AN IMPORTANT CONSTITUENT OF SEA WATER

By L. G. M. BAAS BECKING, A. D. HALDANE and DAVID IZARD

Commonwealth Scientific and Industrial Research Organization and Bureau of Mineral Resources, Canberra

PERCHLORATES, together with iodates and chromates, are known to occur in the Chilean nitre-beds[1-4]. Goldschmidt[3] suggested that these "final products of oxidative weathering" might also occur in other nitre deposits and, perhaps, in the evaporite environment in general. It now appears that both iodates and perchlorates are of widespread occurrence in the natural environment. This article is confined to the consideration of the perchlorates.

The reason why the presence of these oxyhalides has hitherto escaped attention must be ascribed in part to the inadequacy of the analytical methods[5-9]. We have tested most of the reagents described in the literature and the reproducibility of their reactions. Many of the tests for perchlorate suffer from grave disadvantages and have not been sufficiently investigated. There are reagents, like copper pyridine[10], that may yield positive results with pure perchlorate solutions but are of no use when the sample contains high concentrations of other salts. Some reagents seem to be of variable composition. This is particularly the case for reagents which are oxidized by perchlorate, such as α-naphthol, resin of guaiac (guaiacol is always inactive), *p*-phenylene-diamine and hæmatoxylin[11]. It is difficult to obtain two samples of these reagents that react in a similar fashion with perchlorate. Perchlorates are reported to react with amines. We found that no insoluble compounds were formed either with hydroxylamine or with hydrazine. It is possible that perchlorates will enter into combination with the amines occurring in the estuarine environment[12]. About most of the other reagents we will remain silent, as it would take too long to discuss their respective disadvantages[5,6].

After much trial and error we were left with three adequate presumptive tests and with two quantitative methods.

(*a*) *The 'char-reaction'*. In drying paper chromatograms it was discovered that perchlorates, in an acid environment, lower the char-temperature of the filter paper. With Whatman paper No. 544 the following results were obtained:

	Char temperature	Time
No perchlorate	230° C.	Instantaneous
Perchlorate	170° C.	Instantaneous
Perchlorate	160° C.	15 sec.
Perchlorate	105° C.	12 min.
Perchlorate	85° C.	35 min.

Among other substances tested, only chlorates and copper ions behaved in a similar way. As chlorates were never found in the natural environment, copper alone might interfere in special circumstances. For a spot-test, the filter paper is pre-treated with a saturated solution of oxalic acid, and dried. A drop of the sample solution is spotted on to the paper, and if, after heating, a jet-black ring is formed the presence of perchlorate is indicated. In the presence of high concentrations of chloride ion the central area of the spot assumes a reddish-brown colour, which is readily distinguished from the black ring given by perchlorates. The spot test may be applied at concentrations of perchlorate greater than about 100 p.p.m.

Circular chromatograms on 10-cm. paper disks (Whatman No. 41), using alcoholic ammonia according to Lederer and Cohen[9], show, on heating, a black, well-defined ring in the presence of perchlorate at R_F 0·83–0·87, the position agreeing with that obtained by other reagents. Using 0·1-ml. drops, the sensitivity may increase to less than 100 p.p.m.

(*b*) *Formation of strychnine perchlorate*[5,8]. Strychnine sulphate crystals, when placed in a dilute solution of perchlorate, slowly become covered with a felt of hair-like prismatic crystals of the perchlorate. According to the literature, this reaction is specific. If the perchlorate concentration is too high, the strychnine sulphate crystals may become immediately and completely covered with the precipitate, thus blocking further reaction, and the typical appearance is not developed.

(*c*) *Methylene blue*[5,8]. Pure methylene blue chloride, free of zinc, yields with perchlorates a purple, crystalline precipitate. Persulphates (absent in the natural environment) and certain salts of heavy metals may interfere. Although not as specific as the strychnine reaction, it is extremely sensitive and requires only small amounts of perchlorate. The methylene blue reaction has been used in the quantitative determination of perchlorate. There are many difficulties. The results reported here were obtained by using: (1) high dilutions (40 p.p.m.) of freshly prepared pure methylene blue, allowing 20–30 min. for the reaction to become complete, and filtering off the precipitate on a sintered glass filter funnel; (2) equal volumes of 25 p.p.m. methylene blue and sample, allowing 30 min. for the reaction to be completed, after which the solution is centrifuged for 10 min. at 3,000 r.p.m. The methylene blue in the filtrate is determined colorimetrically with a Spekker absorptiometer, using a red filter. Less than 100 p.p.m. perchlorate may be determined in this way, which is very satisfactory when compared with other methods[6]. Further refinement may be obtained by shaking out the molybdenum perchlorate with *iso*propyl–methyl ketone. 1 p.p.m. potassium perchlorate may be detected in this way, using a 'Unicam' spectrophotometer. In the presence of chloride the distribution of the dye between the aqueous and the ketone layer is very slow; it takes several days before equilibrium is established. For this reason, the method has not been further investigated.

(*d*) Fusion with sodium carbonate will convert perchlorate to chloride, which can then be titrated with silver nitrate[13]. This method is suitable only for samples initially low in chloride ion. The removal of the initial chloride ion by precipitation with silver nitrate appears unsatisfactory when small amounts of perchlorate are involved.

(*e*) *Other methods*. No polarographic wave is obtained with perchlorate[14]. No X-ray patterns could be obtained with natural materials or with their concentrates. Goldschmidt[3] points out that in the natural evaporite salts the perchlorate ion probably enters the crystal lattice of gypsum and that this is the reason why no specific perchlorate mineral has been found, although it may be present in amounts of more than 6 per cent in the nitre[13]. Apart from this 'intralattice' effect in gypsum, perchlorates have a tendency to form 'interlattice' combinations with other salts, notably with sodium chloride. As no sufficiently insoluble inorganic perchlorates are known (potassium perchlorate is still fairly soluble), it seems difficult, if not impossible, to enrich a salt sufficiently to obtain an X-ray pattern of a perchlorate. Thus far we have not discovered potassium perchlorate crystals in natural waters, salts or concentrates. However, the strychnine compound could be prepared from a concentrate of a bittern from Dry Creek Salt Works (Imperial Chemical Industries, Ltd.), South Australia, supplied by Mr. C. W. Bonython. By comparing the X-ray pattern of this compound with strychnine perchlorate their identity was established by Mr. W. Roberts, of the Bureau of Mineral Resources. Inasmuch as the chemical tests on this brine concentrate are in harmony with the X-ray findings, we may now assume that substances yielding the presumptive tests described above are indeed perchlorates.

Occurrence of Perchlorates in Nature

The methods discussed above allowed us to establish the order of magnitude of the perchlorate content of various materials (Table 1). The quantities are often considerable—up to 5,600 p.p.m. in Lake Eyre brine, for example.

This is still less than one-third of the saturation value of potassium perchlorate at 20° C. Much analytical work has to be done before more reliable quantitative results are obtained.

Earlier in our work we obtained comparative results on chromatograms with *p*-phenylene diamine, hæmatoxylin and resin of guaiac for various sea-water samples.

After dissolving the blue oxidation product of guaiac resin (at R_F 0·83–0·87) in acetone, the red extinction was measured with a Lange photometer.

The results (Table 2) would suggest that the perchlorate content of sea-water tends to be highest near the coast and that it may decrease far from land and at great depths.

Table 1. CONCENTRATION OF PERCHLORATE ION IN PARTS PER MILLION IN VARIOUS MATERIALS

Not detected

Tapwater (Sydney and Canberra)
Rainwater (several samples)*
Lake Dobson (fresh). Tasmania
Wombat Moor (fresh). Tasmania

Perchlorate Cycle

There is no reasonable doubt that iodide, bromide and chloride enter into a cycle forming, at one stage or another, higher oxidation levels. It has been unfortunate that in the literature the formation of the known oxyhalides seems to have been linked almost exclusively with the nitrogen cycle[2,3]. While nitrogen compounds may play a part in the formation of oxyhalides, there are many other ways in which these compounds may be formed. Although speculation on this matter seems premature, we should like to suggest one possibility which is in harmony with the data at our disposal.

The almost invariable occurrence of iodate (in particulate form) together with the perchlorate in both sea-water and salt suggests that the cycles of these halides are interconnected. We believe this iodate to be of biological origin, but as yet have not sufficient evidence to say this with certainty. Iodate formed directly from iodide or from elemental iodine may react with chloride to yield chlorine[4], some of which may then form perchlorate. We have found that, in the latter connexion, chlorinated distilled water contains perchlorate.

In sea-water the perchlorate is chiefly dissolved, but while none is held by a millipore filter (diameter 0·5μ), some perchlorate is retained by a Seitz asbestos filter. It may have been adsorbed by the asbestos, however. All the iodate is held by the millipore filter.

We are better informed on the breakdown of the perchlorate, at least in fresh-water. A butyric acid fermentation on malt reduced more than half a perchlorate solution (1,000 p.p.m.) in two weeks at 20° C. In the same time, a sulphate reduction brought a similar solution to 85 per cent of its original strength. Even in surface plankton swarms there may be foci of low potential in which this reduction could take place, as Mr. E. J. F. Wood (Commonwealth Scientific and Industrial Research Organization) has isolated both sulphate reducers and purple bacteria from surface phytoplankton (private communication).

Importance of the Halogen Cycle

(*a*) *Physiological.* Chili saltpetre, containing more than 0·5 per cent perchlorate, has long been known to be toxic to plants[13]. Experiments on the influence of perchlorates on growth and on germination are in progress.

(*b*) *Hydrology and oceanography*[15]. The potential variability of the perchlorate in sea-water may influence the chloride content. It has been observed repeatedly (C. Walker, Commonwealth Scientific and Industrial Research Organization, private communication) that the chlorinity of sea-water increased in the second decimal of the pro-mille chlorinity figure after storage. The order of magnitude of per-

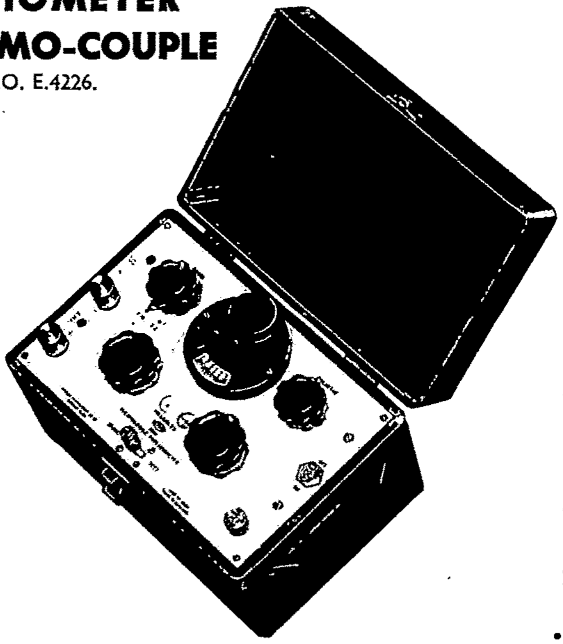
DORAN

POTENTIOMETER
MINI THERMO-COUPLE
CAT. NO. E.4226.

STOCK

This smaller version of our standard Thermocouple Potentiometer has proved very satisfactory both from the point of view of portability as well as accuracy of measurement. The ranges provided cover both rare and base metal thermocouples, and the construction is such that contacts are readily accessible for inspection and cleaning.



Specification :
Battery : Internal 1.5 volts.
Ranges : 20 and 100 millivolts.
Accuracy : 0.01 and 0.05 millivolt
Weight : 7¾ lbs.
Dimensions : 8¾″ × 5¾″ × 5¾″.

PART I

ORGANIC SYNTHESES WITH ISOTOPES

(In two parts)

Since radioactive isotopes became regularly available, at the beginning of the Atomic Age, several thousand labelled organic compounds have been prepared. The synthetic methods used have been hard to find, for they have been scattered throughout the literature. Now this material is all gathered and presented as an encyclopedic source of chemical methods of isotopic synthesis. The style of presentation is that of the well-known *Organic Syntheses*. The literature has been covered through 1955, after which time the number of published isotopic syntheses became markedly less. When several methods for a particular compound were found in the literature, one selected "best" method has been given, with references to the others. Since the procedures were usually chosen for *high yields*, they will be of interest not only when radioactive isotopes are concerned, but in general organic synthesis.

PART I: COMPOUNDS OF ISOTOPIC CARBON

1156 pages	25 illustrations	8 tables	188/-

CONTENTS: 1. Introduction. 2. Acids. 3. Acid Derivatives. 4. Amines. 5. Carbonic Acid Derivatives. 6. Carbonyl Compounds. 7. Ethers. 8. Heterocyclic Compounds. 9. Hydrocarbons. 10. Hydroxy Compounds. 11. Onium Compounds. 12. Sugars and Sugar Derivatives. 13. Steroids. 14. Vitamins.

PART II: ORGANIC COMPOUNDS LABELED WITH ISOTOPES OF THE HALOGENS, HYDROGEN, NITROGEN, OXYGEN, PHOSPHOROUS AND SULPHUR
(*To be published later this year*)

1100 pages	24 illustrations	46 tables	Approx. 188/-

CONTENTS: 15. Isotopic Halogen Compounds. 16. Isotopic Hydrogen Compounds. 17. Nitrogen-15 Compounds. 18. Oxygen-18 Compounds. 19. Phosphorus-32 Compounds. 20. Sulfur-35 Compounds. INDEX, Parts I & II.

SYNTHETIC METHODS OF ORGANIC CHEMISTRY

Volume 12	1958	546 pages	155/-

By W. THEILHEIMER. Most of the references in this volume concern papers published between 1955 and 1957. The index includes volumes 11 and 12, the first two of the third series. It also contains a few additional or revised entries to former volumes.

MACMILLAN BOOKS

Atlas of the Sky

VINCENT DE CALLATAŸ

A unique atlas, containing 72 pages of text and 36 plates, for the use of amateurs of astronomy. Translated and with a Foreword by Sir Harold Spencer Jones, former Astronomer Royal. 'The whole work is simply and most admirably planned.'—*Sphere.* 'It is just what the amateur astronomer wants.'—*Financial Times.* 65*s*

New Intermediate Physics

G. R. NOAKES

A coherent survey of Physics based on the study of wave motion and the law of the conservation of energy. 'In these days and by every standard, this book must be regarded as remarkable value for money. In some 950 pages it covers fully the Advanced Level course and in many places provides much of the material needed by the scholarship candidate.'—*A. M. A.* *With diagrams* 30*s*

General Microbiology

ROGER Y. STANIER, MICHAEL DOUDOROFF and EDWARD A. ADELBERG

This book attempts to present a modern synthesis of microbiological knowledge for university students of the biological sciences. Students new to this subject will find it particularly useful. *With photographs and diagrams* 50*s*

A School Course of Biology

L. J. F. BRIMBLE, B.SC., F.R.S.E., F.R.S.A., F.L.S.

The fourth edition of this well-known, comprehensive text-book has been entirely re-written and enlarged in collaboration with L. M. J. Kramer, and new drawings and photographs added. It should meet the requirements of all candidates for the G.C.E. ('O' level), but in many places attention has been diverted from an actual syllabus, in order to include aspects of an economic and everyday nature in biology which will attract the interest of the student. 18*s*

Inside Story

ENDECOTTS
TEST SIEVES

No crevices to trap particles ; frame and wire cloth are joined as one.

Guaranteed Accurate Manufactured under licence from the British Standards Institution.

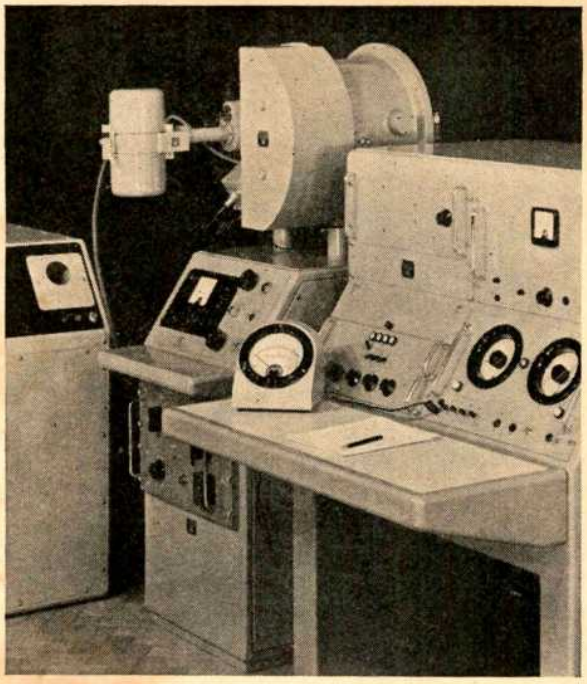
Mechanical Sieving is ideal with Endecotts Sieves—several simultaneous tests are possible with intermediate receiving pans.

British, U.S. Standards and Tyler Equivalents are readily available, many other international standards also supplied.

"Endrock" Test Sieve Shaker saves valuable time and effort of skilled personnel; similar to manual motion but is more consistent, having a regular mechanical action—a time switch controls the length of time for tests.

We operate a **Recovering Service**—if sieving is important to your business, ring or write for literature—or for any advice you require—we'll be glad to help.

ENDECOTTS (FILTERS) LTD.
251 Kingston Road, Merton Park, London, S.W.19.
Telephone: LIBerty 8121/2. Telegrams: ENDFILT, LONDON.



Pins and needles . . .

. . . bridges and bicycles,
we see steel in use all around us.
Steel that has to conform to strict
specifications, to ensure that its qualities
are suitable for its purpose.
Steel contains small quantities of such
elements as carbon, phosphorus and sulphur,
upon which its properties depend.
Because of this, it is essential that
the exact amount of these elements present
in the melt should be known just before
it is poured from the furnace.
That is why so many steelmakers rely
on the spectrograph for their analyses.

¶ The illustration shows a Hilger automatic spectrograph that determines the carbon, phosphorus, and sulphur in steel in a minute and a half. It operates in the far ultra-violet region, and uses fluorite optics housed in a vacuum chamber to prevent absorption of the rays.

HILGER & WATTS LTD

98 ST PANCRAS WAY, LONDON, NW1

THE ENGLISH ELECTRIC CO. LTD.

GUIDED WEAPONS DIVISION

STEVENAGE AND LUTON

ASSISTANT TECHNICAL PERSONNEL OFFICER

Applications are invited from graduate engineers and scientists of about 30 years of age who are interested in gaining experience of technical personnel problems associated with the recruitment, placing, and transfers of laboratory staff.

The post offers an opportunity for men with a purely technical background to obtain administrative experience, and applicants need not be currently employed as Personnel Officers.

Housing assistance may be available. Please write, giving details of experience and qualifications, to Department C.P.S., Marconi House, 336/7 Strand, W.C.2, quoting reference N1391M.

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

RESEARCH IN ELECTRONICS

Scientists are required to lead small teams carrying out original research in electronics. These deal with a wide variety of interesting problems which arise in nuclear physics and which cannot be solved by the techniques and equipment available at present.

A first- or second-class honours degree preferably in Physics or Electrical Engineering, and independent research experience in suitable aspects of electronics are essential. The fields include ultra-fast time measurements, general electronic circuit design, transistor circuit design, information handling techniques and the design of special electronic tubes.

The posts which are in the Nuclear Research Division at Aldermaston are in the grade of Principal Scientific Officer and Senior Scientific Officer.

SALARY:—P.S.O. £1,460–£2,080 p.a.
S.S.O. £1,215–£1,425 p.a.

Contributory Superannuation Scheme. A house or assistance towards legal expenses on house purchase will be available for married officers living beyond daily travelling distance.

*Postcards for application forms to the Senior Recruitment Officer at A.W.R.E., Aldermaston, Berks. Please quote ref. B.*1647/34.

chlorate in sea-water is such that reduction of the perchlorate may even influence the first decimal place.

It may become necessary to prepare sterile standard sea-water from perchlorate-free salts. Stored sea-water should remain in contact with the air so as to prevent the creation of low oxidation potentials and the possible reduction of the perchlorate.

Permanganates and persulphates being absent in Nature, the perchlorate represents the highest oxidation-level of the inorganic environment. While the ion is comparatively inert, it may transfer its oxygen to various phenolic compounds. It may combine with amines present in the natural environment[12], and there is reason to assume that, given sufficient time, it might transfer this oxygen to inorganic substances as well.

Any study on oxidative weathering in saline environments has to take this possibility into account.

FAILURE OF SORBITOL TO REPLACE INTRINSIC FACTOR IN THE GASTRECTOMIZED RAT

By DR. BERNARD A. COOPER*

Thorndike Memorial Laboratory and Second and Fourth (Harvard) Medical Services, Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston, Mass.

EVIDENCE has recently been presented that 'Liptril', a pharmaceutical preparation free of gastric intrinsic factor, may enhance the absorption of vitamin B_{12} from the gastrointestinal tract of man[1] and of the rat[2]. 'Liptril' contains vitamin B_{12} as well as various other vitamins, minerals, preservatives, flavours, and colouring material. However, Greenberg[2] and Chow[1] and their associates are in agreement that the substance responsible for the increased absorption of vitamin B_{12} is D-sorbitol, present in a concentration of 28 per cent. A similar effect was also noted in rats with certain other sugars and sugar alcohols[2].

Greenberg and his associates[2] suggest that the carbohydrate portion of the intrinsic factor may be important in vitamin B_{12} absorption. In the gastrectomized rat measurement of the effect of rat intrinsic factor may conveniently be made[3] with a dose of 0·015 μgm. of vitamin B_{12} labelled with cobalt-60. On the other hand, in the studies of Greenberg and his associates[2] with D-sorbitol on normal rats a much larger dose of the labelled vitamin (1·36 or 1·4 μgm.) was employed. Likewise, Chow and his associates[1] used 50 μgm. instead of the usual 0·5–2·0 μgm. in the Schilling urinary excretion test employed by them in demonstrating the activity of D-sorbitol in man. It therefore appeared to be of interest to learn whether D-sorbitol is effective in the rat, with or without intrinsic factor, in increasing the absorption of a small dose of vitamin B_{12}. Appropriate studies were accordingly undertaken on intact rats, as well as on rats previously subjected to total gastrectomy.

The techniques of total gastrectomy, administration of test materials, and collection and assay of faeces for radioactivity were as described by Nieweg and his associates[3]. Male rats of the Sprague-Dawley strain, weighing 200–250 gm., were subjected to total gastrectomy and allowed to recover for several days from the operation. Normal male rats of similar weight and of the same strain were employed in other experiments. The test solutions were administered by stomach tube to fasting animals, stools were collected for 96 hours thereafter, and the amount of radioactivity excreted was determined and expressed as a percentage of that administered. The test solution consisted of 1 or 2 ml. of a modified, partial aqueous formulation of 'Liptril' prepared without vitamin B_{12} and containing 28 per cent by weight of D-sorbitol, together with 0·5 ml. of water containing 0·015 μgm. of labelled vitamin B_{12} with a specific activity of 565 μc. per μgm. The control solution consisted of 2 ml. of isotonic saline and 0·5 ml. of the same solution of the vitamin.

It was soon noted that diarrhœa was frequent in the normal animals receiving the 2 ml. dose of modified 'Liptril', free of vitamin B_{12} (hereafter called modified 'Liptril') and was invariable in the gastrectomized animals receiving this dose. Consequently, results obtained with animals with diarrhœa are excluded, and in the gastrectomized animals only those obtained with 1 ml. of modified 'Liptril' are reported. No attempt was made to separate the animals which had received modified 'Liptril' from those given isotonic saline as a control, and so a number of the animals received both preparations separated by an interval of at least two weeks.

As shown in Table 1, the normal rats excreted about 50 per cent, the gastrectomized rats essentially all, of the radioactivity of the dose of labelled vitamin B_{12} administered. No certain differences were noted between the average fæcal excretion of radioactivity by those animals receiving modified 'Liptril' and by those receiving saline. This lack of effect applied to both the intact rats and the gastrectomized animals.

In the technique employed here, all or nearly all the radioactivity of a dose of 0·015 μgm. of vitamin B_{12} labelled with cobalt-60 is excreted by the gastrectomized rat[3]. However, the simultaneous administration of 3 ml. of rat gastric juice or of one-half of a

* Modified, partial, aqueous formulation of 'Liptril' prepared without vitamin B_{12} and containing 28 per cent of D-sorbitol.

homogenized rat stomach will reduce the fæcal excretion of radioactivity to approximately that of the normal rat, about 50 per cent of the dose administered. The absence of any such effect with modified 'Liptril' in these gastrectomized rats suggests that, even at the maximum dose tolerated without diarrhœa by the animals, it did not take the place of rat intrinsic factor; nor did twice this amount of modified 'Liptril' enhance the absorption of the small dose of vitamin B_{12} by the intact animal. On the other hand, 'Liptril' free of vitamin B_{12} or D-sorbitol apparently augments absorption of vitamin B_{12} by the intact rat when approximately 100 times as much vitamin is administered[2].

In pernicious anæmia Ross and his associates, and recently Doscherholmen and Hagen[4], have demonstrated that two mechanisms seem to exist for the absorption of vitamin B_{12}. Rapid absorption follows a rather large dose of the vitamin (50–3,000 μgm.) and is independent of or even inhibited by intrinsic factor. On the other hand, a slower, apparently physiological mechanism, dependent upon the presence of intrinsic factor, is required for the absorption of small amounts of vitamin B_{12} (0·5–1·0 μgm.). The substance in 'Liptril' promoting the absorption of large doses of vitamin B_{12} in the rat[2] and in man[1] has been shown to be D-sorbitol. Consequently, those reports, as well as the present experiments, suggest that D-sorbitol affects the rapid mechanism for the absorption of vitamin B_{12} in man described[4] as independent of intrinsic factor activity. Further evidence for this is found in the ability of D-sorbitol and of certain other carbohydrates to enhance iron absorption in both the rat and man[5] as well as calcium absorption in the rat[6]. Other observations in patients underline the importance of the size of the dose of vitamin B_{12} in determining the ability of D-sorbitol to enhance its assimilation. Thus, Chow and his associates failed to observe such an effect in pernicious anæmia when 2 μgm. of radioactive vitamin B_{12} were given during remission, whereas Helen E. Duell[7] has observed enhanced hæmatopoietic activity with D-sorbitol in a few such patients in relapse when the dose of vitamin B_{12} was 15 μgm.

The carbohydrates reported to be active in promoting the absorption of vitamin B_{12}, calcium, and iron in the rat seem to be those classically considered to be absorbed by passive diffusion from the intestine, whereas carbohydrates considered to be absorbed by phosphorylation, such as glucose and fructose, are reported to be inactive[2]. This perhaps further suggests that the action of D-sorbitol does not involve a specific transport mechanism.

We are indebted to Mrs. Felicita Fradera for technical assistance, to Dr. S. M. Greenberg, of Smith, Kline and French Laboratories, for D-sorbitol, and to the Merck, Sharp and Dohme Research Laboratories for the labelled vitamin B_{12}.

DEGRADATION OF BLOOD GROUP-SPECIFIC MUCOPOLYSACCHARIDES BY FICIN AND PAPAIN

By A. PUSZTAI and PROF. W. T. J. MORGAN, F.R.S.

The Lister Institute of Preventive Medicine, London, S.W.1

MUCOPOLYSACCHARIDES composed of carbohydrate and amino-acids firmly bound together are responsible in man for immunological specificity within the ABO and Lewis blood group systems[1]. The specific substances are usually isolated by extraction of freeze-dried secretions or tissue digests with cold 90 per cent phenol solution, the serologically active mucopolysaccharide remaining largely insoluble in this solvent whereas the protein impurities pass into solution[2]. By the use of this simple procedure, followed by fractionation of the specific materials from aqueous solution by organic solvents and/or inorganic salts, it has been possible to isolate and study the properties of the human blood group substances[3]. In spite of the different serological characters of the A, B, H and Le^a substances, they each possess the same qualitative composition and contain the same four sugars—L-fucose, D-galactose, D-glucosamine and D-galactosamine, and eleven amino-acids, none of which is aromatic or contains sulphur.

Proteolytic enzymes have also been used to remove adventitious protein during the isolation and purification of the group substances from materials of human and animal origin, and it has generally been accepted that the specific mucopolysaccharides are not changed by such treatment[4]. A few early observations[5], however, suggested that in certain instances a destruction or modification of the serological character occurs, but where this has been reported the modified substances were not recovered and the physico-chemical changes induced were not determined.

A study of the literature reveals that, almost without exception, the preparation of highly purified specific mucopolysaccharides has involved at some stage treatment with 90 per cent phenol. An attempt was therefore made to isolate the specific substances by a method[6] which did not involve the use of phenol, and to achieve this the native secretions or tissues were incubated with activated ficin at about *p*H 7. It was hoped by this means to remove the accompanying unspecific protein and ultimately to recover unchanged the specific substances. Mucopolysaccharides recovered after treatment with ficin, however, gave solutions of much-reduced relative viscosity, as compared with the materials isolated by means of simple phenol extraction. The ficin-treated group substances were readily soluble in phenol and even soluble to some extent in liquid 95 per cent w/w phenol, whereas specific substances recovered by extraction of the original materials with 90 per cent phenol were largely insoluble in this solvent. The behaviour of relatively homogeneous specific substances on ultracentrifugation and electrophoresis at *p*H 4 and 8 suggested that after ficin treatment they became polydisperse and contained more than a single component. These marked differences in properties indicated that an alteration in the structure of the specific mucopolysaccharides had occurred, but no definite evidence was obtained at that time that the serological properties of the materials were modified.

A closer examination of the substances treated with ficin with those recovered from the same source by simple phenol extraction revealed that the specific substances after treatment with ficin have a lower capacity to neutralize the corresponding antibody in hæmagglutination tests. This reduced activity is not always obvious when cyst fluids or other secretions are given a single short treatment with ficin at *p*H 7, especially when they contain, as they frequently do, a large excess of unspecific protein.

These additional findings prompted a more detailed study of the action of ficin on preparations of specific substances which had been extensively purified by several successive extractions with cold 90 per cent phenol until their analytical composition remained unchanged. To remove possible minor contaminants which might remain, the substances extracted with phenol were fractionated further with ethanol and a fraction, which amounted to about 95 per cent of the whole, separating between 43 and 45 per cent ethanol concentration, was collected. Purified ficin was obtained from dried commercial fig latex by dialysis and fractionation with ammonium sulphate[7]. The material was electrophoretically homogeneous and behaved as a single substance when eluted from a column of Amberlite I*RC*–50 with $0 \cdot 2M$ phosphate buffer (*p*H 5·6). Experiments were also made with crystalline ficin.

A typical hydrolysis experiment was carried out as follows: thoroughly purified *A* substance dissolved in phosphate-citrate buffer at *p*H 4 was incubated at 37° for 16 hours with about 1 per cent w/v ficin, which had been activated with 2 : 3 dimercaptopropanol (B.A.L.). Toluene was added as a preservative. The solution was then saturated with ammonium sulphate, filtered, dialysed free from salt, evaporated under reduced pressure and dried from the frozen state. The treatment with ficin was repeated and the final product was fractionated from 2 per cent w/v solution in 2 per cent w/v sodium acetate solution, by the addition of ethanol. The major part of the substance separated between 47 and 55 per cent v/v ethanol, whereas the original material under similar conditions precipitated completely between the levels 43 and 45 per cent v/v ethanol. The substance treated with ficin was found to be closely similar in composition to the material before treatment, but possessed no more than about 3–6 per cent of the activity of the original A substance, when measured in the same test against natural human anti-A agglutinin. The value for activity showed a smaller reduction when immune rabbit or human serum was used, but the final figure attained varied somewhat according to the specimen of anti-A serum used. Materials separating at higher (50–60 and 60–75 per cent v/v) concentrations of ethanol were relatively small in amount but gave similar analytical figures, and showed an even lower serological activity. Rabbit anti-A serum and pneumococcus type XIV horse anti-serum precipitated strongly when mixed with an equal volume of a 0·1 per cent solution of all these mucopolysaccharide fractions. There was no evidence that the capacity of the materials to inhibit the hæmolysis of sheep cells by anti-A cell immune rabbit serum, and complement decreased significantly. The material remaining in solution in 75 per cent ethanol possessed about 0·2 per cent of the activity of the original A substance; nevertheless, it remained closely similar to the original substance in chemical composition. Typical analytical figures obtained for the products arising from group A substance are given in Table 1. Ficin brings about the changes described over a broad *p*H range (4–7·6). Repeated treatment with ficin of the main fraction, which was precipitated from solution between 47 and 55 per cent v/v ethanol, failed to lower further the serological activity or change the analytical composition (after the fourth treatment with ficin: nitrogen, 4·3; fucose, 24·9; hexosamine, 30·9; reducing sugar, 53·3 per cent) and material soluble in 75 per cent v/v ethanol was no longer formed. Complete serological inactivation, as measured by precipitation and hæmagglutination inhibition tests, however, can be readily brought about by the action of an enzyme preparation obtained from *Trichomonas foetus*[8].

Table 1. ANALYTICAL VALUES FOR THE PRODUCTS OF THE ACTION OF FICIN ON BLOOD GROUP A SUBSTANCE

	Original A substance	Fractions precipitated from ficin-treated A substance				
		Ethanol concentration (per cent)				
		47–50	50–55	55–60	60–75	above 75
Nitrogen (per cent)	5·2	4·4	4·7	4·4	4·4	3·4
Fucose (per cent)	23·4	25·5	23·8	23·4	21·5	17·4
Hexosamine* (per cent)	31·5	32·0	31·6	32·0	30·4	26·0
Reducing sugar* (per cent)	50·0	51·3	53·5	51·4	52·3	57·0
Hæmagglutination inhibition activity (μmoles)	0·5	8	8	16	64	128
Specific optical rotation $[\alpha]_D$	− 50°	−30°	−43°	−42°	−46°	—
Relative viscosity at 20° in water (1 per cent solution)	4·68	2·39	1·51	1·21	1·10	—

* After the materials have been hydrolysed with 0·5 *N* hydrochloric acid for 18 hr. at 100°. Hexosamine is given as 'base'; the reducing values in terms of glucose equivalents.

Similar experiments, in which the step involving purification with ammonium sulphate was omitted and the dialysis waters were concentrated and examined by chromatography for diffusible products, showed that simple sugars and oligosaccharides were not released in demonstrable amounts from the specific substances as a result of treatment with ficin. Amino-acids and/or peptides were usually found in the diffusates, but only in small quantities. Their appearance can be correlated with the small but consistent decrease in the nitrogen content of the material recovered after treatment with ficin, but it has not yet been finally established whether these amino-acids are derived from the specific mucopolysaccharide alone, and the loss in specific activity is due to changes induced by their release, or whether they arise from small amounts of contaminating protein or peptide in the specific substance.

Similar detailed hydrolysis experiments with ficin have been made using H substance, and its general behaviour cannot be distinguished from that described above for A substance (see Table 1). Although as yet studied in much less detail, B and Le^a substances appear to be changed by ficin in a similar manner, again with extensive but limited loss in serological activity.

The specific mucopolysaccharides have been treated with crystalline papain under similar conditions, and here again the same sequence of events has been found to occur; there was a reduction in serological activity to a value equivalent to a few per cent only of the original, and no very obvious change in chemical composition occurred. The results of some preliminary experiments indicate that papain can extend the hydrolysis brought about by ficin, which suggests that these two proteolytic enzymes can act on different peptide structures within the mucopolysaccharides.

The changes observed when ficin acts on the specific substances can be explained most simply by assuming that the materials, which are macromolecular carbohydrate/amino-acid complexes, are degraded by rupture of a limited number of peptide bonds and relatively large carbohydrate/amino-acid units are set free with no release of simple sugars or diffusible oligosaccharides. In support of this suggested mode of attack, there is other evidence which can be briefly mentioned. The extent of the changes induced in the specific mucopolysaccharide depends on the quantity of the enzyme used; definite hydrolysis can still be recognized when a substrate:ficin ratio of 1,000 : 1 is employed. The hydrolysis of the specific substances can be completely inhibited if the ficin is incubated with an equimolar quantity of *para*chloromercuribenzoate before the addition of the substrate and the activity can be restored either by adding a 6–10-fold excess of substances containing free SH groups (B.A.L., cysteine, etc.), or by dialysis of the mercury-ficin compound against 0·01 *M* cystein solution. The ficin used did not contain lysozyme, and crystalline lysozyme had no action on the specific substances as measured by the hæmagglutination inhibition test. The enzyme used did not appear to contain α- or β-galactosidases or β-N-acetylglucosaminidase.

Paramucin, mucus surface epithelium, and other water-insoluble complexes containing mucopolysaccharide can be readily brought into solution by digestion with ficin or papain at neutral *p*H, and this procedure was recently suggested as the basis of a method for obtaining the specific substances from these and other biological materials[6]. Now that it has been shown that ficin and papain bring about limited, but nevertheless important, changes in the specific materials, it is obvious that these enzymes should not be used for the isolation of the specific substances, if native mucopolysaccharide preparations are required.

If the present views concerning the structures associated with blood group specificity within the ABO and Lewis systems are correct, then it is the non-reducing end residues of certain oligosaccharide units which are mainly responsible for the serological character on which group specificity depends. As a result of thorough treatment with ficin there has been no loss from the specific substances of carbohydrate, either in the form of simple sugars or as diffusible oligosaccharide fragments, and therefore presumably the specifically reactive structures are still intact in spite of the considerable fall in inhibition titre observed. It is not surprising, therefore, to find that the major part of the materials formed as a result of the limited proteolysis react strongly in specific anti-A precipitation tests.

It is clear that the chemical changes induced in the specific substances by ficin or papain are very different from those brought about by extracts of *Trichomonas foetus*[8], many bacterial culture filtrates[9], and hepato-pancreas preparations from certain snail species[10], etc., where crude or purified enzyme systems bring about an extensive release of small diffusible sugar units together with complete destruction of the characteristic serological specificity. Treatment of the specific substances with ficin and papain, on the other hand, appears to hydrolyse only a few of the potentially susceptible peptide bonds and to give rise to a limited number of smaller fragments resistant to ficin, closely similar in composition to that of the original substance, and in this manner induce changes not brought about by any method previously described. The use of these proteolytic enzymes of plant origin and possibly of other similar ones from animal tissues opens up new possibilities for an experimental approach to the isolation of relatively small structural entities containing unchanged carbohydrate units joined to peptides and ultimately, perhaps, devoid of amino-acids, and thus constitutes a valuable tool for the study of mucopolysaccharide structure.

Full details of these experiments will be given elsewhere.

This investigation was aided by a grant from the Nuffield Foundation. One of us (A. P.) wishes to thank the Ford Foundation for a studentship.

Seasonal Illumination of a Circumpolar Earth Satellite at its Extreme-Latitude Orbit Point

Optical tracking of Earth satellites is the only means of determining their motion with such precision as to render measurements of air density significant. This, however, can only be done when the satellite is sunlit, considering that a flashing beacon (which has been suggested) would relatively quickly run out of power. I shall discuss the insolation of Earth satellites revolving on orbits similar to those of the Russian *Sputnik*.

The summit points of the orbit or points nearest the pole define a locus, *L*, which is centred on the Earth's axis, provided that the inclination of the orbit is different from zero. Verticals passing through the summit-points and their sub-points define a conical surface with its vertex at the centre of the Earth. This locus *L* (Fig. 1) forms the base of the cone, the intersection of which, with the illumination cylinder *I.Cy*, defines the illuminated arc *abc* and its complementary arc *ac*, which is in shadow. Let the angles of these arcs be, respectively, $2(\pi - K)$ and $2K$

Consider an orbit with inclination, $i = 65°$, and a height of passage at the summit-point, $h = 400$ km. (this is, somewhat schematized, the case of the Russian Earth satellites). Then we may derive *K* from the following relations and quantities (Fig. 1c):

$$\cos K = \frac{\cos \nu - \cos \varphi \cos \mu}{\sin \varphi \sin \mu}$$

where $\mu = (90° - i) = 25°$ and, if *P* is the polar distance of the Sun, $\varphi = (180° - P)$. The angle ν is given by:

$$(R + h) \sin \nu = R$$

where *R* is the radius of the Earth (6,350 km.) and *h* is 400 km. Thus:

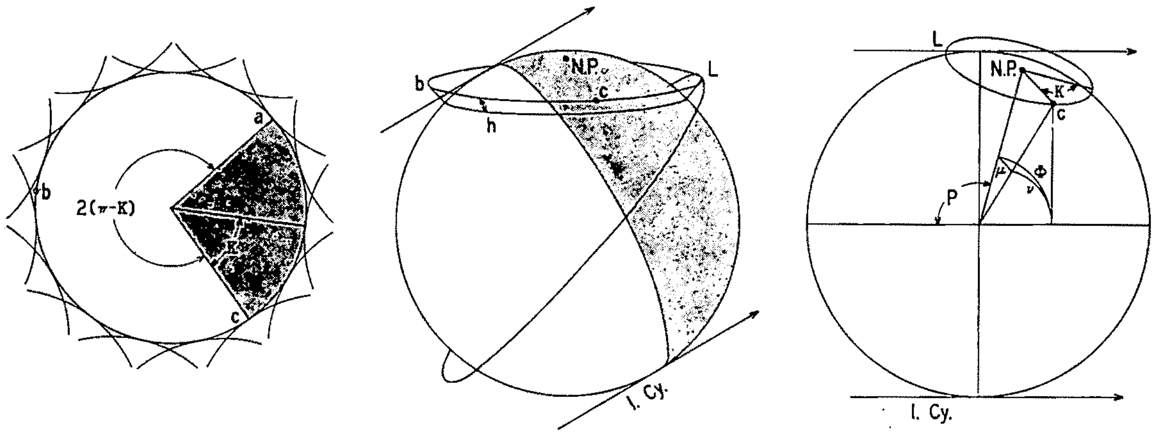
$$\cos K = \frac{0 \cdot 33901 + \cos P \times 0 \cdot 90631}{\sin P \times 0 \cdot 42262}$$

Table 1

P		*K*		$2(\pi - K)$	
Deg.	min.	Deg.	min.	Deg.	min.
084	50.0	000	00.0	360	00.0
090	00.0	036	39.5	286	40.0
100	00.0	064	07.5	231	45.0
110	00.0	085	48.7	188	22.6
113	26.5	093	10.0	173	40.0
120	00.0	108	10.7	143	38.6
125	00.0	121	31.2	116	57.6
134	49.0	360	00.0	000	00.0

Arcs $ab = 2K$ and $abc = 2(\pi - K)$ are functions of the polar distance of the Sun. Table 1 gives the values of these arcs corresponding to certain values of *P*.

These values are plotted in Fig. 2. The inner scale of the abscissæ gives the arc $2(\pi - K)$, and the outer scale gives the hours, *H*, before and after solar noon at which the summit-point would still receive the Sun's rays. When the satellite goes over that northernmost point of the orbit (for the northern hemisphere), it will catch the Sun's rays even if the rest of the orbit is in shadow. Actually, due to the refraction, the illuminated part of the orbit will be more than a point. For the northern hemisphere the summit-point of the orbit will be in constant sunlight during April 5–September 8. For the southern hemisphere these dates will be October 8–March 6.



(*a*) (*b*) (*c*)

Fig. 1

These values of *P* change considerably with the height, *h*, at the summit-point.

The *h*-curves of Fig. 2 give the values of $2(\pi - K)$ and the hours of insolation of the summit-point as a

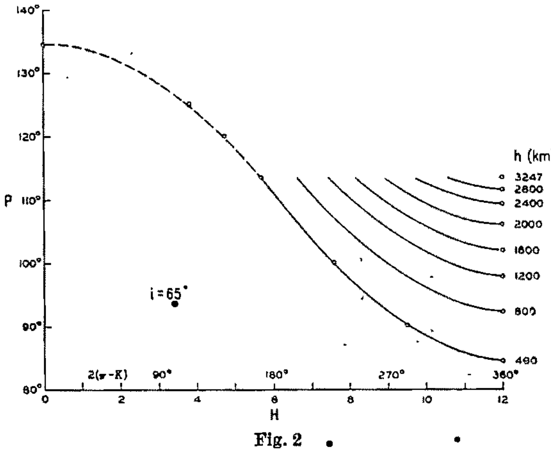


Fig. 2

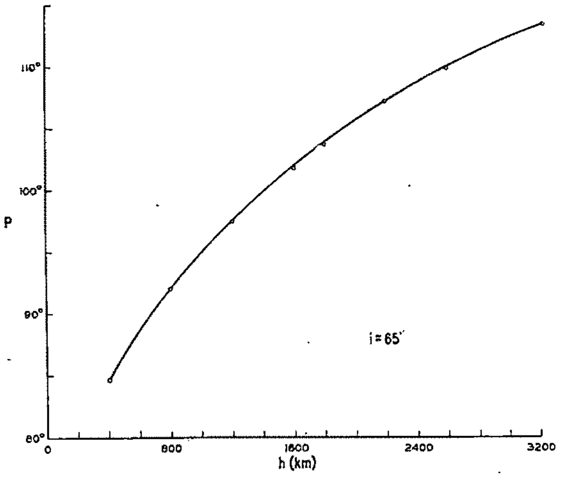

Fig. 3

function of the polar distance of the Sun, P. Table 2 gives the values of P required to give constant insolation throughout 24 hr. as a function of h.

Table 2

h (km.)	cos $(90 - \nu)$	$(90 - \nu)$ Deg.	$(90 - \nu)$ min.	P Deg.	P min.
400	0·94074	019	49.0	084	49.0
800	0·88811	027	21.5	092	21.5
1,200	0·84106	032	45.0	097	45.0
1,600	0·79784	036	59.5	101	59.5
1,800	0·77914	038	49·0	103	49.0
2,200	0·74269	042	02.3	107	02.3
2,600	0·70950	044	48.5	109	48.5
3,247	0·66327	048	27·5	113	27.0

These values are plotted in Fig. 3. All-year-round insolation of summit-point and therefore of the entire locus L will occur if the height of the satellite at the summit-point is 3,247 km., since for this value $P = 113°\ 27'$, which is the polar distance of the Sun at the winter solstice for either hemisphere. Atmospheric refraction, which will increase the illuminated arc, has not been taken into consideration.

Interface Couples in Crystals

Joel and Wooster[1] have discussed cases in which 'volume couples' can arise in certain classes of crystals due to strains, and have mentioned that in such cases the stress tensor is not symmetrical ($\sigma_{yz} \neq \sigma_{zy}$). Actually, it is possible for asymmetry of the stress tensor to arise in any class of crystals, due to distributed couples which are acting across an interface rather than being distributed throughout a volume. These distributed interface couples have the same relation to the distributed volume couples that stresses have to distributed body forces.

Let χ_{yz} represent the component of the interface couple per unit area acting on a y-face and having its moment vector in the z-direction. For equilibrium across an interface, $\chi_{yz} = \chi_{-y-z}$. In the presence of these surface couples the moment equilibrium of a differential element can be found as noted in Fig. 1. Neglecting the effect of any volume couples for brevity, the condition for equilibrium of moments about the z-axis is:

$$\left(\sigma_{xy} - \sigma_{yx} + \frac{\partial\chi_{xz}}{\partial x} + \frac{\partial\chi_{yz}}{\partial y} + \frac{\partial\chi_{zz}}{\partial z}\right) \mathrm{d}x\, \mathrm{d}y\, \mathrm{d}z = 0 \quad (1)$$

Equilibrium of the other components of moments gives similar equations. Thus the deviation from the classical theory of elasticity in this case is due to the derivatives of the interface couples. It should be noted that the moments due to stress gradients of the type $\partial\sigma_{xx}/\partial y$ are higher-order differentials.

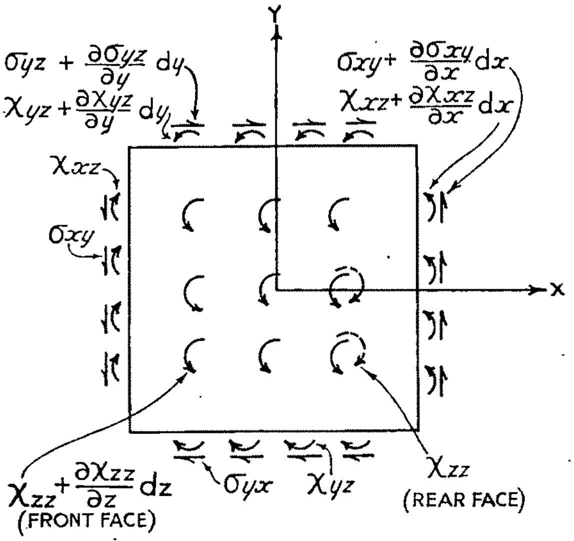
The transformation law for the interface couples may be derived in a manner similar to that for stresses, by considering moment equilibrium of a tetrahedron. In terms of the direction cosines $l_{ij'}$ between the i- and j'-axes,

$$\chi_{i'j'} = \sum_{i=1}^{3} \sum_{j=1}^{3} \chi_{ij} l_{ii'} l_{jj'} \quad (2)$$

Thus the interface couples are tensors. It should be noted that the stresses do not become involved in the transformation law. The interface tensor is not in general symmetrical (that is, $\chi_{yz} \neq \chi_{zy}$), so that even in two dimensions the Mohr's circle transformation would not be applicable.

It seems likely that the 'strains' resulting from these interface couples are the lattice curvatures $\varkappa_{ij}$ discussed by Bilby, Bullough and Smith[2]. Relations between the interface couples and the curvatures would add 45 elastic constants. Interaction between the usual stresses and strains and the newer concepts of interface couples and curvatures, which would occur in the case of crystals of the symmetry discussed by Joel and Wooster, would bring the total number of elastic constants to $(18^2 + 18)/2$, or 171.

An order-of-magnitude estimate of the importance of interface couples in a crystal may be obtained by assuming that the atomic forces causing interface couples are of the same order as those causing ordinary stresses. The interface couple χ acting on one face of a unit cell of dimension a gives rise to a couple χa^2. The moment arm of this couple is no greater than the order of the lattice spacing a, so that $\chi a^2/a \leqslant 0\ (F)$. But the interatomic forces are also of the order of the normal stress, $E\varepsilon$, times the area



Y

(FRONT FACE)
σ_{yx}
χ_{yz}
χ_{zz}
(REAR FACE)

Fig. 1

of the face: $F = 0\ (E\varepsilon a^2)$. Thus the interface couples will be no greater than $\chi \leqslant 0\ (E\varepsilon a)$. For the gradients of the couples to be of the same order as the shear stresses, so that, from equation 1, $\sigma_{xy} - \sigma_{yx} = 0\ (\sigma_{xy}) = 0\ (\sigma_{xx})$, the difference of the shear stresses is of the magnitude of the stresses themselves:

$$\frac{\partial \chi}{\partial x} = 0\left(Ea\,\frac{\partial \varepsilon}{\partial x}\right) = 0\ (E\varepsilon)$$

$$\text{or}\quad \frac{\partial \varepsilon}{\partial x} = 0\left(\frac{\varepsilon}{a}\right)$$

Such high gradients of strain would be expected only around singularities such as cracks and dislocations.

Interface couples may also be of importance in laminated plastics reinforced by fibre. If alternate plies are laid with the fibres perpendicular to each other, and the whole assembly pulled at 45° to both fibre directions, there will be couples acting on the interfaces between plies wherever fibres cross over each other. The sign of these interface couples changes from one side of a ply to the other, so that there would be large gradients of the interface couples and hence $\sigma_{xy} \neq \sigma_{yx}$.

Molecular Orbitals and Vibrational Potential Function of Nitryl Fluoride

In their work on the electronic structure of the N_2O_4 molecule, in which the N—N bond was found to be a π-only bond, Coulson and Duchesne[1] were led to consider the structure of a single NO_2 molecule. This can be represented using in particular two nitrogen lone-pair electrons, three π-electrons associated with the whole O—N—O framework and four σ-electrons. The aim of this communication is to see to what extent this picture may be used as a basis for the study of NO_2F in terms of molecular orbitals. In this molecule, contrary to what occurs in N_2O_4, N_2O_3 and N_2O_2, we should expect a normal σ-bond for NF. Such a bond should be obtained by promoting one of the lone-pair electrons to the π-orbital labelled Q by Coulson and Duchesne[1]. This gives rise to a total of four π-electrons, distributed in the P and Q molecular orbitals, whereas the remaining lone-pair σ-electron is coupled with the $2p_z$ electron of fluorine.

Let us now consider the effects which can be expected from this redistribution of electrons on the properties of the NO_2 group. As the Q orbital may be assumed to be $O \leftrightarrow O$ anti-bonding, the ONO angle has to be larger in NO_2F than in NO_2, whereas the corresponding bending force constant should be smaller. On the other hand, as the Q orbital is $N \leftrightarrow O$ non-bonding (or perhaps very slightly anti-bonding), the change in the NO bond-lengths ought to be insignificant, though the variation of the hybridization character at the nitrogen atom caused by the angle opening might give rise to a small bond shortening.

Table 1

Force constants	NO_2F	NO_2*	NF_3†
f_{NF}	4·3– 5·3		4·28–5·27
f_{NO}	11·0–11·8	10·42	
f_{ONO}	0·2– 0·5	1·099	
f_{FNO}	1·5– 1·6		

* From ref. 5.
† From values given in ref. 6.

The validity of this model must be tested, and a comparison with the vibrational potential function is valuable. (It is to be noted that the molecular dimensions reported[2] for NO_2F are affected by the fact that the value for the ONO angle had to be assumed.)

In Table 1 are given the limits between which the force constants of NO_2F (expressed in 10^5 dynes/cm.), which is of C_{2v} symmetry[2,4], are found to vary when making reasonable assumptions of the values of the coupling constants. (The accuracy for the values of the interaction terms is too low to make any suggestion here. It is, however, fairly certain that $f_c(NO/NF)$ and $\gamma_c(NF/ONO)$ are respectively positive and negative.) The results have been deduced from a general potential function, introduced earlier by Duchesne[3]. The infra-red and Raman data have been taken from the work of Dodd, Rolfe and Woodward[4]. For comparison, the corresponding constants for NO_2 and NF_3 are also given in the table.

First, it is seen that the NF stretching constants are almost the same in NO_2F and NF_3, in agreement with our model. Secondly, on going from NO_2 to NO_2F a large weakening of the bending constant (about 65 per cent) and a small strengthening of the NO bonds (about 10 per cent) are observed. This also was to be expected on the basis of the general properties of the Q orbital, the anti-bonding character of which is now estimated. The extension of these results to the discussions of molecules such as NO_2Cl and NO_2Br is premature, due to lack of experimental data. It is to be hoped that the present work, which may be compared with Duchesne's work on the electronically excited molecules[3], may indicate a fruitful way for testing and evaluating the properties of the molecular orbitals.

An Oxidation Reaction Highly Dependent on Pressure

The rates of oxidation of metals in gases at high temperatures are frequently influenced by the pressure of the gas. The dependence on pressure, which has in some cases been theoretically explained[1], is generally small, often according to some fractional power[2]. During an investigation of the oxidation of aluminium alloys in high-temperature steam we have found a very much greater dependence on pressure.

In our experiments, the alloy "Aereal 1" (aluminium + 2·5 wt. per cent nickel), chosen for study because of its good resistance to high-temperature water[3], was exposed to dry steam at 325° C. and pressures from 550 to 1,500 lb./in.^{2} for periods up to 160 hr. Oxidation was assessed by the gain in weight of the specimen—a valid measure, since wholly adherent films were formed. Oxidation/time curves for each pressure followed a parabolic equation ($w = Kt^m$), where $m = 0{\cdot}48$. The constant K was found to be markedly dependent on pressure; assuming $K \propto p^n$, values of n from 3·9 to 4·3 were obtained, so that the parabolic rate constant was approximately proportional to the fourth power of the pressure.

Since the reaction followed a parabolic relation with time at all pressures, implying that the rates are inversely proportional to film thickness, the controlling process must be diffusion through the oxide film. It is on the latter, therefore, rather than on a surface reaction of the oxide/steam interface, that variations of steam pressure must exert their effect. No certain explanation of the effect can be offered at present, but it seems likely that, under the conditions of the experiments, the composition of the film is significantly changed by variations of steam pressure.

Studies of the equilibrium between steam and bulk aluminium oxides indicate that corundum (α-Al_2O_3) replaces böhmite (γ-$AlO(OH)$) as the stable phase at about 385° C. [4]. This transition temperature may be rather lower when the oxide forms as a surface film, as is true of the analogous change from bayerite ($Al(OH)_3$) to böhmite. (For the bulk substances, the transition temperature[5] is 130° C.; but, on corroding aluminium, böhmite forms the film[6] above 60° C.). The conversion of $AlO(OH)$ to Al_2O_3 involves the elimination of water, so that at lower pressures the film composition should be nearer α-Al_2O_3, which might well be more protective than böhmite. If the experimental temperatures were near that of the transition at the pressures studied, a large dependence of composition, and thus of corrosion-rate on pressure, could occur. Preliminary results at 350° C. (and similar steam pressures) suggested not only that rates of corrosion were lower than at 325° C., indicating a more protective film, but also that the dependence on pressure was less, as might be expected further from the transition temperature.

Additional experiments, including a study of the composition of the oxide films, are proceeding and will be reported elsewhere.

Thermal Decomposition of Hydrogen Peroxide Vapour

KNOWLEDGE of the decomposition of hydrogen peroxide vapour is of considerable importance to the developing understanding of unimolecular reactions and also of the oxidation of many gaseous fuels. McLane[1] and Giguère and Liu[2] claimed the overall homogeneous decomposition to be first-order. Satterfield and Stein[3] claimed that the decomposition occurred by a chain reaction the overall order of which was 1·5. We have carried out an extensive investigation of the decomposition and shown that it is non-chain and second-order (that is, the rate can be expressed as $k[H_2O_2]\,[M]$) up to pressures of at least 1 atmosphere of nitrogen). We have further shown that the first step in the decomposition must be the second-order reaction:

$$H_2O_2 + M \rightarrow 2OH + M \qquad (1)$$

Hoare and Walsh[4] had earlier given reasons why (1) would be expected to be second-order at ordinary pressures. The efficiency of M in bringing about reaction (1) decreases in the order $H_2O_2 > H_2O > CO_2 > N_2 > O_2 > He$.

Using our values for the efficiencies of the gases which played the part of M in the work of McLane[1], Giguère and Liu[2] and Satterfield and Stein[3], we have calculated, from the results of these authors, second-order rate constants which, after proper correction for heterogeneous effects, agree excellently one with another and with our own results. The rate constant of (1), when M is H_2O_2, is found to be $10^{15{\cdot}4} \exp(-48{,}000/RT)$ l.mole^{-1} sec.$^{-1}$.

A full account of this work will be published elsewhere.

Deuterium Exchange in Polypeptides

OBSERVATIONS on the rate of deuteration of the NH groups in solutions of proteins in heavy water (see, for example, ref. 1) have shown that in some proteins there is both a fast and a slow exchange, and it has been conjectured that those NH groups which exchange slowly are hydrogen-bonded in α-helix arrangements, whereas the fast reaction is associated with solvated NH groups. This possibility can be more profitably examined in solutions of a simple polypeptide such as poly-γ-benzyl-L-glutamate, where the conditions for α-helical or random, solvated coil forms are now well-known[2,3]. Doty and Yang[3] have shown that in mixtures of dichloracetic acid and ethylene dichloride, samples of poly-γ-benzyl-L-glutamate of high molecular weight may exist either in α-helix or in random coil forms, according to the composition of the solvent.

We have followed the rate of deuterium exchange by measuring the strength of the hydrogen-bonded peptide NH band at about 3,300 cm.$^{-1}$. Since chloroform is more transparent in this region than ethylene dichloride, we have used a mixture of chloroform and O-deuterated dichloracetic acid as solvent. By measurement of the dispersion of optical rotation, we have found, as expected from the work of Doty and Yang, that with 10 per cent dichloracetic acid in chloroform (v/v) the polymer is all in the α-helix form. In pure dichloracetic acid only the random form is found[4].

If poly-γ-benzyl-L-glutamate is dissolved in O-deuterated dichloracetic acid, and chloroform is added to give a 10 per cent solution of the acid, the spectrum of the solution is found to show no NH band, even when the time required for solution and observation is reduced to less than an hour. The deuterium exchange evidently proceeds very rapidly. When, on the other hand, the polymer is first dissolved in chloroform, and 10 per cent of O-deuterated dichloracetic acid is then added, a strong NH band is seen in the spectrum; this band does not diminish appreciably in a period of days, and deuterium exchange is very slow. There is therefore no doubt that, under the conditions described with a polymer concentration of 0·5 per cent w/v, the random, solvated coil allows the deuterium exchange to proceed very much more quickly than the α-helix form. It would, however, be rash to suppose that there are not other important factors to be considered in interpreting deuterium exchange in protein solutions.

Quantitative Separation of Nitrogenous Organic Bases using Ammonium Reineckate

DURING a study of the reineckates of a series of clinically important basic compounds, the mechanism of the reaction between the bases and ammonium reineckate was studied. It was found that the formation of the complexes depends on the basicity of the compounds, and that under suitable pH conditions certain bases can be separated quantitatively from one another. A brief discussion of the reaction mechanism on which the separation is based is presented here, and a full report on this work will be published elsewhere.

When a base (B) is dissolved in water the following equilibrium exists:

$$B + H_2O \rightleftharpoons BH^+ + OH^- \qquad (1)$$

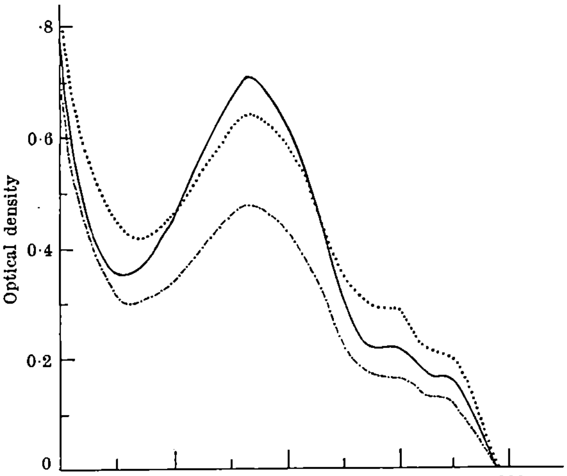

Fig. 1. Spectra of strychnine. ———, The standard strychnine, 2 mgm./100 ml.; –·–·–, from liver; ......, from liver with caffeine added. Solvent, 95 per cent ethyl alcohol

With the addition of an ammonium reineckate solution the conjugate acid, BH^+, thus formed will react with the $[Cr(NH_3)_2(SCN)_4]^-$ ions arising out of the dissociation of ammonium reineckate and form the relatively insoluble reineckate complex, thus:

$$BH^+ + [Cr(NH_3)_2(SCN)_4]^- \rightarrow BH[Cr(NH_3)_2(SCN)_4] \qquad (2)$$

The equilibrium represented by equation (1) is disturbed and more conjugate acid will be formed to replace the reineckate salt as it is removed. It is obvious that in an aqueous solution the formation of the reineckate complex depends on the formation of the conjugate acid BH^- from the base B.

The equilibrium between the conjugate acid and water is:

$$BH^+ + H_2O \rightleftharpoons H_3O^+ + B \qquad (3)$$

The extent to which this equilibrium will exist will depend not only on the strengths of the bases but also on the pH of the reaction media. The relation between these variables may be expressed by an equation of the form

$$\log \frac{[B]}{[BH^+]} = pH + pK_b - 14 \qquad (4)$$

where pK_b is the dissociation constant of the base.

In practice, the pK_b values of the bases can be obtained, and by using equation (4) the required pH of the reaction media can be calculated; this will either be favourable or unfavourable for the formation of a particular reineckate. Thus piperidine (pK_b 2·8) and pyridine (pK_b 8·6) can be separated in an ammonical solution of ammonium reineckate at pH 9. After the separation of the piperidine reineckate, acidification of the filtrate to pH 2 aids the formation of pyridine reineckate.

In cases where the compounds are not very soluble in an aqueous solution the reaction may be carried out by dissolving the bases in chloroform or benzene and shaking it with an aqueous solution of ammonium reineckate of the required pH. The separation of codeine (pK_b 6·05) and caffeine (pK_b 13) at pH 7 was effected in this way. Tables 1 and 2 show recoveries of piperidine and pyridine, and codeine and caffeine, respectively, from mixtures.

Table 1. Recovery of Piperidine and Pyridine from Mixture

Piperidine used (mgm.)	Pyridine used (mgm.)	Piperidine recovered (mgm.)	Pyridine recovered (mgm.)
83·0	147·3	82·6	145·0
150·8	38·7	151·2	37·3

Table 2. Recovery of Codeine and Caffeine from Mixtures

Codeine used (mgm.)	Caffeine used (mgm.)	Codeine recovered (mgm.)	Caffeine recovered (mgm.)
52·4	256·3	51·4	252·7
15·7	482·4	15·2	477·5

The separation of basic putrified materials (mainly ptomaines) from basic nitrogenous poisons from highly decomposed human liver has been effected by precipitation of the interfering substances in ammoniacal solution of pH 9. The purity of the recovered strychnine from highly putrified human livers using this procedure is demonstrated in Fig. 1.

A dibasic substance may be treated as a mixture of two bases since it possesses two different dissociation constants. In agreement with the reaction mechanism just discussed many of the dibasic antihistamines studied gave the di-reineckate derivatives in acid solution (pH 2); in water (pH 7) only the mono-reineckates are obtained. Equation (4) also shows that the reineckates of very weak bases can only be formed in strongly acidic media. Urea, which is reported as not forming a reineckate[1], has yielded a reineckate under these conditions.

Thus, with a knowledge of the reaction mechanism, ammonium reineckate has become a very versatile and useful reagent. It can be used for the separation of certain mixtures of bases besides forming derivatives with them which are useful for identification and determination. Molecular weights of the conjugate bases can be obtained by spectrophotometric analysis of the complexes. The free bases can also be regenerated easily by using ion-exchange resins.

Swift Dumas Nitrogen Estimation

A novel apparatus, Fig. 1, has been designed which enables the rapid estimation of nitrogen by the principle of Dumas and Pregl[1].

The apparatus (patent applied for by Loughborough Glass Co., Ltd., Loughborough) comprises two concentric combustion tubes C_1 and C_2. The centre tube C_1 has a side-arm A passing through the outer tube C_2. C_2, having twice the diameter of C_1, is sealed at one end, and has a B.S. cone $C19$ at the other end.

When initially setting up the apparatus, a copper gauze plug N is inserted into the far end of tube C_1, followed by a layer of fine copper oxide wire CuO, 15 mm. long, which is kept in place by an asbestos plug P_1. Tube C_1 is stoppered with a rubber bung R_s, and the annular space between the tubes is packed with fine copper oxide for 50 mm., followed by a 30 mm. filling of copper wire and finally copper oxide wire within a distance of 50 mm. from cone $C19$. The filling of tube C_2 is kept in place by asbestos plug P_2. Side-arm A is connected to a carbon dioxide generator using a rubber tube R_T and a screw clip T_1. An asbestos sheet X is arranged over the combustion tube as in Fig. 1, and, with carbon dioxide passing through, the tubes are heated and left to cool.

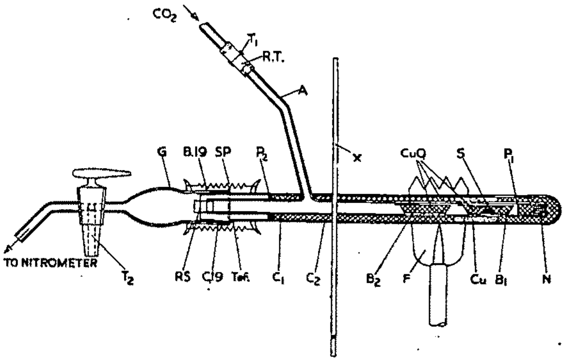

Fig. 1

Through G, which consists of a $C19$ socket and a three-way tap T_2, the apparatus is connected to the nitrometer. The cone and socket joint is sealed with a 'Teflon' sleeve *Tef*, the connexion being secured with springs.

For analysis, a sample of 3–7 mgm. is weighed into a suitable container, which is then placed in a metal boat B_1 and covered with copper oxide. With tap T_1 open, bung R_s is removed and boat B_1 is placed in the far end of tube C_1. A second boat B_2 filled with copper oxide is placed in front of it. Bung R_s is replaced and cone $C19$ with the 'Teflon' sleeve attached to it, connected to socket $C19$.

With tap T_1 open and tap T_2 open to the atmosphere, carbon dioxide is bubbled through for about 1 min. Tap T_2 is then opened to the nitrometer. As soon as micro-bubbles are obtained and the froth is taken off in the nitrometer, the combustion can be started.

Tap T_1 is closed and tap T_2 opened. Flame F is placed under the part of the tube containing the copper layer and slowly moved towards the end of the tube. Combustion is complete after about 5 min., when escape of bubbles into the nitrometer will stop. Tap T_2 is then closed and tap T_1 opened. T_2 is then adjusted so that bubbles escaping into the nitrometer follow each other closely. The flame is removed and the tube left to cool. After about 5 min. carbon dioxide micro-bubbles will appear again in the nitrometer. Tap T_2 is connected to the atmosphere and after the usual period the volume of nitrogen is read.

Results obtained using the procedure described are given in Table 1. More details will be published later.

Table 1

	Sample (mgm.)	Percentage nitrogen (theory)	Percentage nitrogen (found)
Dinitrobenzene	4·546	16·67	16·60
	4·778		16·63
	4·694		16·71
	5·251		16·62
Azobenzene	5·060	15·37	15·30
	4·664		15·38
	3·512		15·47
	6·578		15·34

My thanks are due to Miss Y. Law and Mrs. V. Taylor for most efficient assistance; to Mr. Evans for skilful work in making this apparatus; to Mr. Lambie for encouragement throughout and to the Directors of Fisons Pest Control, Limited, for permission to publish this communication.

A Minor Anthocyanin Pigment of Sweet Cherry

THE sweet cherry contains an anthocyanin, keracyanin, the rhamnoglucoside of cyanidin, which was first isolated by Willstätter and Zollinger[1]. Robinson and Robinson[2] indicated the presence of a cyanidin-3-monoside in the skins of small black cherries. The complete picture of the anthocyanin pigments of any one species of sweet cherry, however, has not been reported.

Recently a method of isolation of the natural anthocyanins involving silicic acid chromatography has been developed in this laboratory, and proved useful in pigment studies in sour cherries[3] and the wild strawberry[4]. The present work was undertaken to extend this method to the case of sweet cherries[5].

The crude anthocyanin pigments of sweet cherries (*Prunus avium* L., var. Windsor) were prepared by the procedure previously described for sour cherries[3]. Two pigment components of the crude anthocyanin mixture were separated from the silicic acid column, employing the upper phase of the solvent system, *n*-butanol/acetic acid/water/benzene (4 : 1 : 5 : 2 v/v) for developing and elution.

The major anthocyanin pigment, which separated as the upper band on the silicic acid column, comprised about 85 per cent of the total pigments, as compared with the 15 per cent for the minor pigment, which constituted the lower band. These proportions of the two anthocyanins were the same both in the skin and in the highly coloured flesh of the sweet cherry.

The major anthocyanin pigments, after being eluted from the silicic acid column, were crystallized from methyl alcohol containing 2 per cent hydrochloric acid in the characteristic brown-orange needle clusters of antirrhinin as isolated from sour cherries[3]. This major fraction was shown to be cyanidin-rhamnoglucoside or keracyanin by the same procedure as used for the identification of the antirrhinin from sour cherries[3].

The minor fraction of pigment was obtained as tiny red spherical crystals after elution from the silicic acid column and crystallization from methyl alcohol containing 2 per cent hydrochloric acid. On paper chromatograms this minor pigment has R_F values identical with a synthetic sample of chrysanthemin, cyanidin glucoside, in several solvents, but these numerical values were only very slightly greater than those of synthetic idaein, cyanidin galactoside, which was also used as a control. Both the minor pigment and the chrysanthemin showed identical absorption curves with maxima at 515 and 280 mμ in 0·5 per cent hydrochloric acid solutions. In 60 per cent ethanol containing 0·1 per cent hydrochloric acid, both the major and minor anthocyanin pigments of the sweet cherry showed the same maximum absorption at 535, 333 and 282 mμ.

The crystalline anthocyanidin from acid hydrolysis of the minor pigment was identified as cyanidin by the tests previously employed for the cyanidin obtained from sour cherries[3]. From the sugar solution after hydrolysis, an osazone was prepared with phenylhydrazine, with crystalline forms of glucosazone, m.p. 205° alone or admixed with authentic glucosazone. That this sugar moiety was glucose was confirmed on paper chromatograms using several of the solvent systems of Jermyn and Isherwood[6], and found to have the same R_F values as authentic glucose. Galactose, fructose, and mannose were included as controls. The minor anthocyanin pigment of the sweet cherry is therefore chrysanthemin.

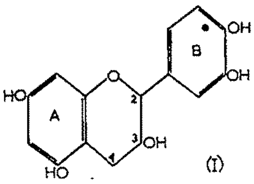
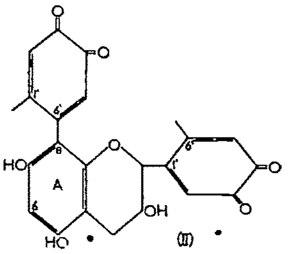
Leuco-Anthocyanins as the Possible Precursors of Tannins

ROUX has recently reported[1] that he had found leuco-anthocyanins in wattle extract and discussed biochemical aspects of these substances. The occurrence of leuco-anthocyanins in wattle and certain other tannin extracts was first referred to by Hillis in 1954[2] and further discussed by him in 1956[3]. At the same time the suggestion was put forward that leuco-anthocyanins could be the precursors of certain tannins[3,4]. Other workers also have confirmed the presence of leuco-anthocyanins in tannin extracts, and in particular in wattle extract (ref. 5 and King, H. G. C., and White, T., personal communication, May 1956).

Freudenberg[6] and others have suggested that condensed tannins are polymerized catechin (catechin I). Hathway and Seakins[7] have obtained evidence to support the view that a catechin polymer formed at *p*H 4–8 has linkages as in II. They have shown the similarity of this structure to those of the tannins from *Acacia catechu* and *Uncaria gambir*.



(I)



(II)

The leuco-anthocyanins which have been characterized possess a 3,4-flavandiol structure, and a polymerization similar to that of catechin would be expected to take place. However, it is difficult to reconcile the ease with which anthocyanidins are obtained from polymerized leuco-anthocyanins with such a structure.

A study of the amount and type of linkages in tannins has shown that those in a catechin polymer differ from those in certain tannins, and that those in the latter differ between themselves.

The method of examination involved the determination of the amount of formaldehyde which reacted with the sample at *p*H 4–5 for 30 min. at room temperature and for 3 hr. on a steam bath. We have found (unpublished work) that the catechol fragment does not react under these conditions, and thus the number of vacant reactive positions in the *A* ring can be determined. If substitution occurred in the *A* ring, its ability to react with formaldehyde would be reduced.

To avoid changes in the leuco-anthocyanins during purification crude samples of tannins were examined. They were commercial extracts of wattle bark (*Acacia mollissima*), 'Myrtan' (from wood and bark of *Eucalyptus wandoo*), mangrove cutch (from barks of *Rhizophora mucronata*, *Rhizophora apiculata* and *Bruguiera gymnorrhiza*). Kino collected from *Eucalyptus calophylla* was also examined. The tannin contents given in Table 1 have been determined by reaction with formaldehyde under acid conditions[8] and the formaldehyde uptake has been expressed on the basis of these figures.

Table 1. PROPERTIES OF CATECHINS AND TANNINS

Sample	Tannin (per cent)	Formaldehyde uptake		Anthocyanidin produced*	
		30 min. at 20° C. gm./gm. tannin	3 hr. at 100° C. gm./gm. tannin	Per cent	Calculated† as:
(+)-Catechin	116	0·146	0·082	—	—
(+)-Catechin polymer‡	103	0·062	0·048	—	—
Kino	99·6	0·041	0·059	12·1	cyanidin and pelargonidin (1 : 1)
'Myrtan'	67·7	0·011	0·043	10·5	cyanidin and pelargonidin (1 : 1)
Cutch	77·7	0·027	0·040	9·9	cyanidin and delphinidin (1 : 1)
Wattle	94·9	0·016	0·065	7·1	cyanidin

* Produced by heating with butanol and hydrochloric acid (ref. 10).
† Using values of Schou (ref. 11).
‡ Prepared at *p*H 8 phosphate buffer (ref. 9).

From the results in Table 1 it may be calculated that 1·62 moles of formaldehyde reacted with each mole of (+)-catechin, whereas 0·61 moles reacted with each basic unit of a (+)-catechin polymer[9]. This loss of one available position on polymerization supports the view that it is of the head-to-tail type.

When chromatograms of the tannins were sprayed with vanillin-hydrochloric acid, it was found that kino contained an appreciable portion of mobile flavans, whereas 'Myrtan' contained very little and none could be detected in the cutch. This spray reagent does not permit a reliable comparison of wattle extract with these tannins. Wattle produced the lowest amount of anthocyanidin from the leuco-anthocyanins on heating with butanol–hydrochloric acid[10] (Table 1). One of the factors possibly responsible for this low yield is that different types of linkages may exist in the wattle tannin.

The greater reaction of formaldehyde (formaldehyde uptake) with kino than with the other tannins at room temperatures may be due to the higher amount of monomeric flavans. However, this formaldehyde uptake is still lower than that of catechin or catechin polymer, showing that in these conditions there are fewer reactive positions in the *A* rings. The commercial tannin extracts showed different amounts of blockage to formaldehyde in the *A* ring.

Table 1 shows that, whereas the formaldehyde uptake of catechin polymer and catechin decreased on heating, it increased in the case of tannin extracts, the increase being lowest for kino and highest for wattle. The above decrease was found to be due to expulsion of formaldehyde during polymerization (unpublished work). While this reaction may occur in the tannins, the overall effect is an increase in formaldehyde uptake on heating. Some of this behaviour could be due to a difference in reactivity under different conditions. On the other hand, the results are consistent with the view that a labile grouping is split off from the *A* ring under the conditions of the test. It is known that polymeric flavandiols break down readily when heated with alcoholic hydrochloric acid. Thus, it is possible that they are also broken down under the conditions of the formaldehyde reaction, liberating further positions for attack by formaldehyde. If polymeric flavandiols are linked differently in the various tannins so that some are broken down to the monomers more readily than others, then different formaldehyde uptakes could be obtained on heating (Table 1).

In addition to the different amounts of reaction with formaldehyde, catechin polymer did not react with vanillin/hydrochloric acid, whereas the tannins examined did so. Consequently, the grouping that is linked to the *A* ring must be of such a nature that it does not de-activate this ring[10] for the vanillin/hydrochloric acid reagent.

Further distinction between catechin polymer and the tannins was shown by spectral data. At *p*H 8 catechin polymer showed a maximum at 410 mμ (see also ref. 9). This maximum was not observed in freshly prepared solutions of the tannins at *p*H 8, but on standing, cutch only showed maxima at 410 and 500 mμ. Thus, cutch contains a structure capable of change to one showing a spectrum similar to that of *Acacia catechu* and *Uncaria gambir* tannins[7].

These results will be discussed fully elsewhere.

Characterization of Ficin

THE general attributes of ficin and its enzymic action have not been thoroughly described in the literature. The work of Winnick *et al.*[1] showed conclusively that ficin was a sulphydryl enzyme. More recently the kinetics of ficin on arginine derivatives have been studied[2]. In the present communication its electrophoretic and ultracentrifugal behaviour are described. The optimal conditions for activity and stability were also established. In further characterization of its properties, the effect of acetylation of its free amino-groups on the activity and stability was studied.

To prepare a sample suitable for electrophoretic and ultracentrifugal studies a procedure was adopted to permit proper equilibration of the crystalline suspension of enzyme with the buffers desired and to ensure a depressed oxygen level. 25 mgm. of ficin was dissolved in 3 ml. of buffer and inserted into a 'Cellophane' bag which was slipped over a test tube to form a thin layer of solution around the tube. The sample was then immersed in 400 ml. of buffer kept cold in an ice-bath, through which nitrogen had been passed for 15 min. Rapid dialysis was carried out by shaking the entire apparatus for 2 hr. while the gas was continuously bubbled through the buffer.

The electrophoretic and ultracentrifugal patterns indicated the relative homogeneity of the protein. The sedimentation constant was calculated to be 2·66 S. and was found not to vary with the *p*H. The isoelectric point is at *p*H 9·0.

The *p*H optimum for proteolytic activity of ficin, employing the method of Kunitz but with 0·01 *M* cysteine present, was determined. A broad optimum from *p*H 6·5 to 9·5 was observed.

Acetylation of the free amino-groups of ficin was carried out in a solution half saturated with sodium acetate and 0·15 *M* potassium cyanide. 100 mgm. of ficin dissolved in 5 ml. of this medium, cooled in an ice-bath, was acetylated with 0·6 ml. of acetic anhydride by adding aliquots of 0·1 ml. over a 1 hr. period. The *p*H was maintained above 4·0 throughout the reaction. 40 per cent of the amino-groups were acetylated as determined by ninhydrin colorimetric analysis. Neither the activity nor *p*H optimum was altered by this modification. From the fact that acetylation with acetic anhydride, which is specific for amino-groups[3], did not impair enzymic activity it may be concluded that most of the amino-groups are not essential.

The effect of varied concentrations of three reducing agents, cysteine, potassium cyanide and dimercaptopropanol, on the activity of ficin was also investigated. The results are summarized in Fig. 1. Activation by cysteine was constant between 5×10^{-3} and 5×10^{-2} *M* concentrations, likewise the activation by dimercaptopropanol remained constant but at a lower level. In contrast, the activity of the enzyme increases with rising concentrations of potassium cyanide to a maximum at 0·075 *M*.

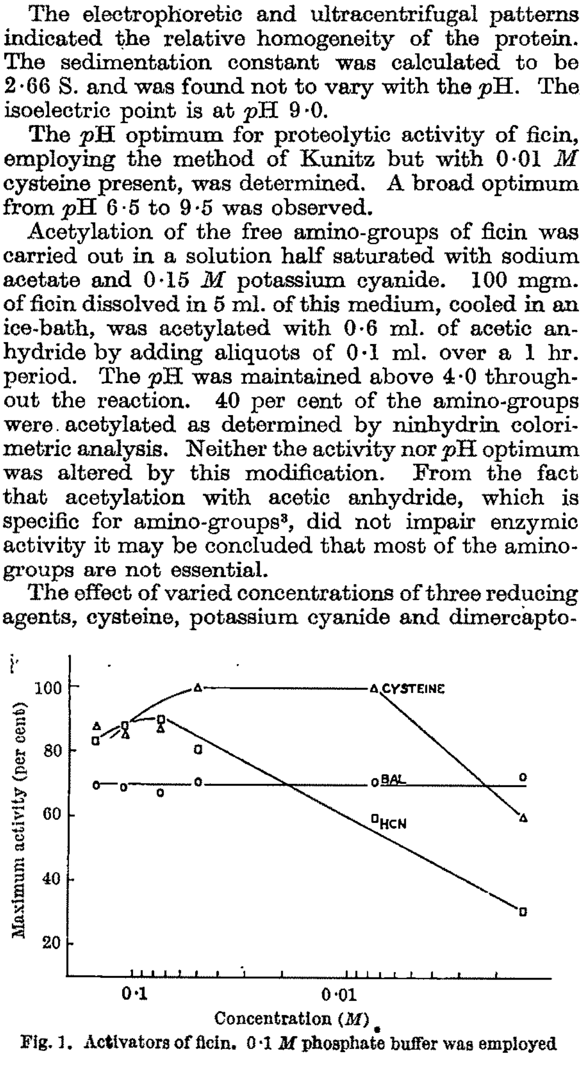

Fig. 1. Activators of ficin. 0·1 *M* phosphate buffer was employed

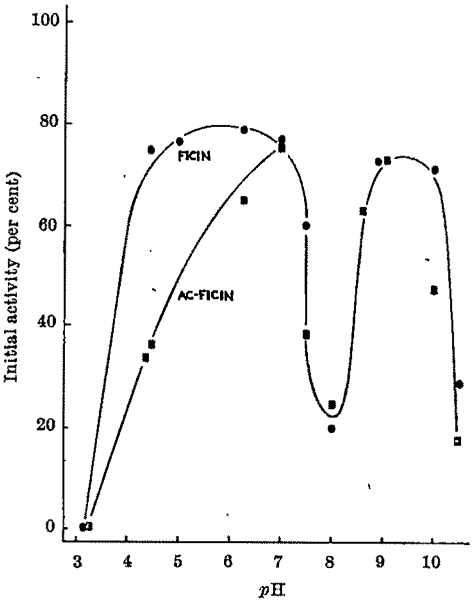

Fig. 2. *p*H stability of ficin and acetylated ficin. The enzymes were incubated for 2 hr. at 50° C. The 0·05 *M* buffers employed are as follows: glycine, *p*H 2·5–3·5; sodium acetate, *p*H 4·0–6·0; sodium phosphate, *p*H 6·0–8·0; sodium borate, *p*H 8·0–9·5; glycine, *p*H 9·5–10·5. 0·01 *M* cysteine was included in each buffer

The stability of ficin was investigated in 0·05 *M* buffers containing 0·01 *M* cysteine at a concentration of 0·33 mgm. per ml. An incubation period of 2 hr. at 50° C. was employed in these studies. The enzyme is stable between *p*H 4·5 and 9·5 except for a narrow zone around *p*H 8·0. These results are recorded in Fig. 2. The acetylated enzyme, which is also depicted in the same figure, presents similar stability properties in neutral or alkaline media, but in acid media it is considerably less stable than the native enzyme. The minimum exhibited by ficin is dependent, most probably, on the rate of auto-oxidation of cysteine rather than a property of the enzyme itself. This zone of instability near *p*H 8·0 can be effectively altered by increasing the concentration of cysteine. It was found that 0·025 *M* cysteine was optimal for stabilizing the enzyme at *p*H 8·0.

Employing 0·025 *M* cysteine, the *p*H stability was redetermined. The enzyme exhibited a more normal optimal stability near *p*H 7·5. Thus the true stability of the enzyme is that which is observed under these conditions of higher cysteine concentration.

The loss of stability in the acid-range upon acetylation of enzymes was previously noted with other enzymes[4-6]. It has been suggested that the groups governing the stability of the native enzyme do not necessarily influence the stability of the acetylated form. The principle that a few key groups are responsible for preservation of the characteristic native secondary structure of proteins can be maintained, provided it is extended to include the possibility that by redistributing overall charges through acetylation other groups may assume this function.

This study was supported by a grant from the U.S. Atomic Energy Commission.

Separation of Chalcones, Flavanones and Flavonols by Chromatography with Polyamide

POLYAMIDE had been used as an adsorbent in chromatography by Carelli, Liquori and Mele[1], as well as by Grassmann, Hoermann and Hartl[2], for the separation of phenols. Recently, Hoerhammer, Wagner and Leeb[3] used it for the separation of flavones and their glycosides, and for the quantitative removal of tanning substances from plant extracts containing flavones.

The complete conversion of chalcones into flavanones is very unusual, and separation by recrystallization is often difficult. It is possible, however, to fractionate chalcones and flavones on a column with powdered polyamide; the chalcone is retained in the upper part of the column, whereas the flavanone is readily eluted with water, aqueous alcohol or aqueous acetone respectively. By this means the simple chalcones can be separated from the corresponding isomeric flavanones; for example, 2-hydroxy-, 4′-hydroxy-, 4′-methoxy-, 3′-methoxy-4′-hydroxy-flavanones. The chalcone that remains in the upper part of the column can be eluted with absolute methanol. If plant extracts are used that contain both chalcones and flavanones, for example butin and butein, the best separation is obtained by aqueous alcohol mixtures. The plant extracts are either dried on, or triturated with, polyamide and the combination placed on a polyamide column. The flavanone is first eluted with mixtures of water and alcohols or ketones, and then the chalcone with the pure solvent. The concentration of the solvent mixtures used for the separation depends on the substance, and is found by the usual alteration of the elution medium in sorption chromatography.

It is often not easy to isolate pure flavanoids, as distinct from the fraction containing these substances, and the process often involves considerable losses of substance[4]. Chromatographic procedures are especially important in this connexion but all the usual substances known as adsorbents cannot be used for the separation of flavonols, especially those that adsorb these compounds irreversibly. Polyamide is an adsorbent that has not hitherto been examined in detail in this respect.

In further work on the hydroxy phenyl-benzo-γ-pyrones it was found that separation of flavonol and flavanonol was possible on a column of polyamide. For these investigations a crude sample of dihydroquercetin that contained a small amount of quercetin was used. The extract obtained from the crude flavanonol by means of diethyl ether was dried on powdered polyamide, and then put on a column containing the same adsorbent made up in water. By elution with aqueous ethanol (20–30 per cent of ethanol) the dihydroquercetin was first obtained and then, by elution with pure ethanol, the quercetin. Both of them were paper-chromatographically pure.

I wish to thank Dr. D. W. Glennie, of the Oregon Forest Research Center, Cornwallis, for the dihydroquercetin.

Reactivity of Sulphonyloxyl Groups with Halides in the Carbohydrate Series

IT has recently been shown[1] that refluxing 6-O-mesyl-1 : 2-3 : 4-di-O-*iso*propylidene-D-galactopyranose[2] (i) and 3 : 5-O-benzylidene-6-O-mesyl-1 : 2-O-*iso*propylidene-D-glucofuranose[3] (ii) with potassium fluoride in ethanediol, yields the 6-deoxy-6-fluoro-D-galactopyranose and D-glucofuranose derivatives, respectively. A notable difference in the reactivity of the two sugars towards potassium fluoride was found (Table 1).

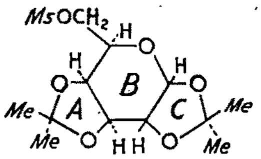
Table 1

Compound	Temperature (°C.)	Time (min.)	Per cent yield of fluorosugar
6-O-Mesyl*-D-galactose derivative (i)	200	75	60
6-O-Mesyl-D-glucose derivative (ii)	200	2·5	75

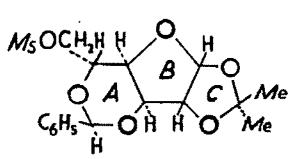
* Mesyl = $-SO_2CH_3$.

A similar qualitative difference in the reactivity of terminal sulphonyloxyl groups of the above D-galactose and D-glucose derivatives has also been observed in the case of iodine exchange reactions, using sodium iodide in acetone (review by Tipson[4]). It is to be expected that the difference in size (and electronic properties) between the iodide and fluoride ions will be one of the many factors which will influence the reactivity of the sulphonyloxyl groups. These results with fluorine and iodine exchange reactions, however, suggest the importance of the actual stereochemistry of the sugar molecule in exchange reactions of this type.

Structures (I) and (II), representing the D-galactopyranes (i) and D-glucofuranose (ii) derivatives, respectively, in their most stable *cis*-anti-*cis* (rings *ABC*) steric arrangement, are written in accordance with the convention suggested by Mills[5a]. It is significant that if ring *B* in (I) and ring *A* in (II) retain their most stable *C*1 chair conformation[6], then the residue $—CH_2O\mathit{Ms}$ is equatorially disposed in (I) and axial in (II).



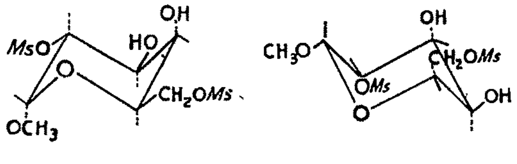
(I)



(II)

It has already been pointed out by Mills[5b] that in iodine exchange reactions, terminal axially disposed sulphonyloxyl groups in *cis* bicyclic diacetals are more readily replaced than equatorial. The fluorine and iodine exchange reactions on (I) and (II) support this view.

It is interesting to note that when (I) is converted to methyl 2 : 6-di-O-mesyl-D-galactopyranoside (III) iodine exchange at C_6 under identical conditions now proceeds much more readily[7]. This may be due to the fact that the removal of the *iso*propylidene groups from (I) now permits the —CH_2OMs residue of (III, *C*1) to take up an axial disposition (III, 1*C*).



*C*1 1*C*

(III)

Further experiments with carbohydrates of known and fixed conformation are in progress designed (*a*) to establish by kinetic studies the influence of steric factors and size of attacking anion on the reactivity of sulphonyloxyl groups, and (*b*) to provide a means of distinguishing between axial and equatorial substituents in carbohydrates where conformation is uncertain.

This work is being supported by a grant from the University of California, Los Angeles, and a grant to Dr. E. M. Gal from the National Institute of Neurological Diseases and Blindness, U.S. Public Health Services (No. *B*-1159).

Itaconicoxidase: an Enzyme from an Ultra-Violet-induced Mutant of *Aspergillus terreus*

During an investigation of the metabolic patterns of ultra-violet-induced mutants in *Aspergillus terreus* Thom[1,2], a soluble, cell-free enzymatic extract, that can oxidize itaconic acid to itatartaric acid, was prepared from the mycelium of a morphologically altered variant.

Cell-free extracts are obtained from surface cultures of the organisms, grown at 28° C., on 100 ml. portions of the medium described in a previous publication[2]. The mycelial pad covers the surface 4–6 days after inoculation. The original culture medium is replaced by 100 ml. distilled water, and the mycelium is allowed to stand in this water for 1 hr. at room temperature. All subsequent operations are carried out in the cold-room. The mycelium is washed with several portions of ice-cold water and is then ground in a mortar with 3 ml. of 0·3 *M* citrate buffer, *p*H 4·16, in the presence of about 1·5 gm. of glass beads. The paste is diluted with 7 ml. of citrate buffer and centrifuged at 1,500*g* for 20 min. at 0° C. The supernatant is passed through a filter paper, yielding an opalescent solution with a slight orange–tan colour. Such solutions have *p*H values between 4·1 and 4·2, and contain some itaconic acid, or itatartaric acid released from the cells during the grinding process.

The enzymatic oxidation reaction of itaconic acid was followed manometrically by standard Warburg techniques in air at 37° C. The total volume was 3·2 ml., containing 1·5 ml. of 0·25 per cent itaconic acid substrate in citrate buffer; 1·5 ml. cell-free enzyme in citrate buffer, *p*H 4·16; and 0·2 ml. of 2 *N* potassium hydroxide were in the centre well.

The other details of the manometric methods and culture conditions, as well as chemical analytical methods used for sugars and acids, the irradiation techniques for the production of the mutations, and the selective work are described in preliminary studies[3].

Typical results of manometric studies of the oxidation of itaconic acid by enzymes prepared from the mycelium of the parent strain (*A*) and of the mutant (*B*), as well as oxygen uptake by enzyme controls in the absence of substrate (endogenous respiration, *E*) are shown in Fig. 1. The enzymatic oxidation of itaconic acid expressed as percentage of the original quantity is shown in Fig. 2. The enzyme obtained from the mutant, which is most active over the *p*H range 4·0–4·2, readily oxidizes itaconic acid forming approximately stoichiometric amounts of itatartaric acid. On the other hand, the cell-free extracts prepared from the unirradiated parent strain did not oxidize itaconate.

The dependence of oxygen consumption on age, concentration, *p*H, inhibitors and oxygen pressure

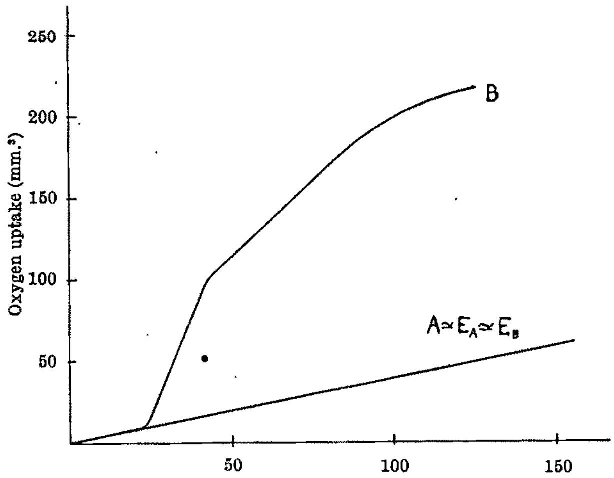

Fig. 1. For key see text

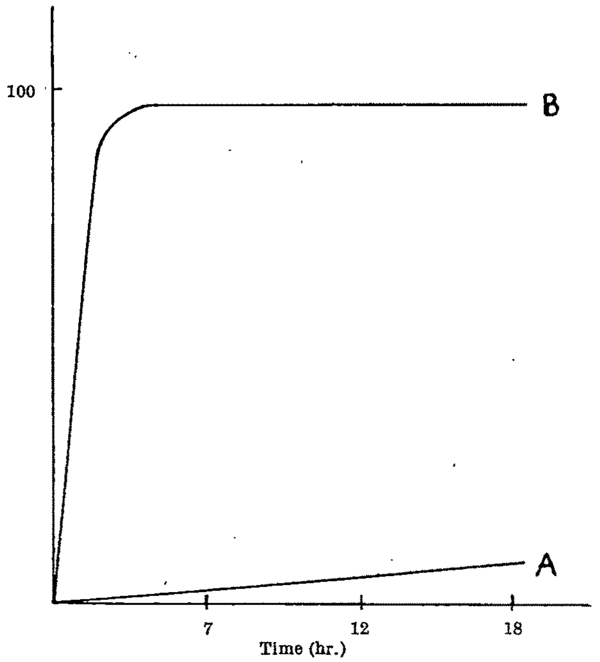

Fig. 2. For key see text

was tested. The oxygen consumption was found to be largely independent of the itaconic acid concentration, and the rate of oxygen uptake decreased with time. The course of oxygen uptake can be divided into two parts, an initial rapid phase, and a second, very slow phase. As the pH is decreased, the rate of itaconic oxidation increases, the oxygen consumption at pH 4·2 being about twice that at pH 7. Cyanide, hydroxylamine and iodoacetic acid, even at concentrations of 0·01 M, have no effect on the oxidation of itaconic acid. Dialysis does not decrease the activity.

The rate of oxidation is proportional to the oxygen pressure, the increase on changing from air to oxygen being generally 100–200 per cent.

Uptake and Utilization of DL-[2-^{14}C] Mevalonic Acid by *Hevea brasiliensis*

THE high efficiency of incorporation of DL-3-hydroxy-3-methyl-[2-^{14}C] pentano-5-lactone (DL-[2-^{14}C] mevalonic acid) into cholesterol in rat-liver homogenates was first shown by Tavormina, Gibbs and Huff[1], who concluded that the lactone could provide an active 5-carbon isoprenoid unit which was used in direct biosynthesis. It was further found that this unit was derived from the lactone by elimination of C_1 as carbon dioxide[2]. These results have been confirmed and extended to squalene biosynthesis[3-5], the pattern of isotopic labelling determined by degradation agreeing with that required for the synthesis of squalene from intact 5-carbon units[3]. Further proof of a general utility of the lactone in isoprenoid biosynthesis is shown by its incorporation into β-carotene in *Phycomyces blakesleeanus* and carrot slices[6], and in *Mucor hiemalis*[7]. The present communication describes briefly the further extension of this field to the uptake and utilization of DL-[2-^{14}C] mevalonic acid by a rubber-producing plant, *Hevea brasiliensis*.

The plants used were 2-year old seedlings, grown in a greenhouse. They were in active growth, and carried large healthy leaves. The uptake of [2-^{14}C] mevalonic acid was best carried out by applying a solution in neutral phosphate buffer to the upper surfaces of leaves, or to lightly scraped areas of the main-stem. To aid uniform leaf application, a trace of wetting-agent ('Tween') was added to the solution. Hypodermic injection was unsuccessful, even when applied to the soft upper stem tissues.

Absorption of the lactone by the leaves was rapid, the count-rates of the upper and lower surfaces being about equal after 5 hr., thereafter remaining almost unchanged. Translocation of activity through the plant did not occur, even to neighbouring untreated leaves, and none could be induced by tapping the plant at several points along the stem. After two days the active leaves were harvested, washed thoroughly with water, ground with sand, and extracted with warm water. All the activity was water-soluble (total count-rate 12,750 c.p.m.), and re-extraction of the aqueous solution with petroleum-ether resulted in the transfer of 52 per cent of its activity. It was shown by paper chromatography that all the activity remaining in the aqueous solution was due to unchanged mevalonic acid. The petroleum-ether extract was chromatographed on a column of 'Celite', and eluted with the same solvent. At least four coloured components were resolved, of which a yellow pigment, which ran with the solvent front as a diffuse band, was completely separated from the remaining bands. This first fraction contained 96 per cent of the activity applied to the column. The residual activity on the column was eluted in the same position as a control addition of [2-^{14}C] mevalonic acid.

The absorption spectra of the active pigment in several solvents agreed closely with those known for α-carotene, and this identity was confirmed by the dextro-rotation shown by the pigment solutions. If it is assumed that only one of the enantiomorphs is physiologically active, the above results show that virtually all the available mevalonic acid absorbed by the leaves was converted to α-carotene.

Application of mevalonic acid to the stem was designed to show whether its efficient use for carotene synthesis in leaves was masking a possible alternative use for rubber synthesis. Again, absorption was rapid, activity moving down the stem from the point of application to appear in the lower newly formed side-shoots and leaves after ½ hr. No activity could be detected moving up the stem.

After three days, leaf activity accounted for about 50 per cent of the total (5 × 10^5 c.p.m.) applied to the stem, and was completely soluble in water. In this case, however, no activity had been incorporated into the carotene fraction, and only a small amount was due to unchanged mevalonic acid. Paper chromatography with a solvent system of n-butanol/water/90 per cent formic acid (10 : 10 : 3 by volume) showed most of the leaf activity to be associated with a single component (R_F 0·12), which probably possessed more polar groups than mevalonic acid (R_F 0·72).

The remainder of the plant, namely, the main stem and side-shoots, was reduced to a fine pulp, and extracted successively with water, ethanol, acetone, ether, and benzene. About 30 per cent of the applied activity was recovered in the aqueous extract, and 20 per cent in the ethanol extract. All other extracts and residues were inactive.

The component with R_F value 0·12 appeared in both aqueous and ethanolic solutions, the latter also containing an active substance (R_F 0·93) which was probably a carboxylic acid.

It may be concluded that, under the conditions of these experiments, mevalonic acid was not incorporated into rubber in *Hevea*, and that it was converted in the stem to products unable to enter the pathway of carotene synthesis which can operate with high efficiency in the leaves.

Fuller details of this work will be published elsewhere at a later date.

Action of Testosterone Propionate and 4-Chlorotestosterone Acetate on Protein Synthesis *in vitro*

The protein anabolic activity of testosterone propionate is well established[1]. It has been shown that an increase in the rate of uptake of labelled glycine occurs in slices of kidney from mice treated with this substance[2]. Incorporation of labelled glycine into liver proteins does not seem to be affected.

As the action of testosterone propionate on protein synthesis might depend on the condition of the tissue, we have studied the incorporation of glycine-1-^{14}C into slices of resting and regenerating livers from animals treated with testosterone propionate.

The effects of a new compound, 4-chlorotestosterone acetate, recently synthesized by Camerino, Patelli and Vercellone[3], have also been studied. This substance possesses powerful myotrophic and weak androgenic activity, as measured by increase in weight of levator ani muscle and ventral prostate gland, respectively[4]. Having greater anabolic and lesser androgenic effects than testosterone propionate similarly administered, it may have considerable therapeutic value as an anabolic agent.

Castrated male rats, weighing 200–250 gm., were used throughout our experiments. They were treated subcutaneously with 2 mgm. of testosterone propionate or 4-chlorotestosterone acetate once a day for three days. The first injection was done 2 hr. after partial hepatectomy in the case of the animals with regenerating liver. At the end of the treatment (72 hr. from the start, 74 hr. from hepatectomy) the rats were killed by decapitation, the livers quickly removed and sliced by hand with a razor. The slices were then placed into the main chamber of a Warburg flask containing 3·0 ml. of phosphate-saline[5]. After 10 min. equilibration, the labelling reaction was started by transferring 2 μc. (3·4 μmoles) of glycine-1-^{14}C in a volume of 0·4 ml. from the side-arm into the main chamber of the flask: this was within 30 min. of the death of the animal. The labelling reaction lasted 1 hr.; the experimental conditions and counting techniques were the same as described by Bernelli-Zazzera and Guidotti[5].

The results are shown in Table 1.

Table 1. INCORPORATION OF GLYCINE-1-^{14}C INTO THE PROTEINS OF SLICES OF RESTING OR REGENERATING LIVERS FROM ANIMALS TREATED WITH TESTOSTERONE PROPIONATE OR 4-CHLOROTESTOSTERONE ACETATE

Counts/min./mgm. of protein. Means of five experiments ± S.E.

	Resting	Regenerating
Controls	165·3 ± 14·0	257·8 ± 40·2
Testosterone propionate treated	152·9 ± 10·8	326·0 ± 36·1
4-Chlorotestosterone acetate treated	165·1 ± 21·6	409·6 ± 47·9

Sum of squares between experiments, within conditions = 73,274·75 (8 d.f.).

The Bartlett test is not significant. Therefore we made an analysis of variance, considering that three rats (control and one treated with each drug) were used throughout one experiment. It was possible to conclude that: (1) slices of regenerating livers incorporate glycine at a rate significantly higher than that of resting livers ($P < 0{\cdot}01$). (2) Slices from rats treated with testosterone propionate or 4-chlorotestosterone acetate incorporate glycine at a rate significantly higher than untreated controls ($P < 0{\cdot}05$). (3) There is no difference between the effects of the two treatments ($P > 0{\cdot}05$). (4) The effects of the treatments largely depend on the state of the tissue ($P < 0{\cdot}05$); this can be seen from Table 1, where the treatments are effective in enhancing glycine incorporation into liver proteins only in the case of regenerating livers, when the restoration of cell structures takes place and the rate of protein synthesis reaches its maximum. Therefore, the hypothesis that testosterone propionate and 4-chlorotestosterone acetate are mainly active on the synthesis of cell proteins is not inconsistent with our results.

Effect of Atmospheric Contaminants on Paper Chromatography of Urinary Indole and Phenol Acids

Samples of human urine have been examined for indole and phenol acids as a matter of routine in this laboratory for several months; the methods used for extraction and two-dimensional paper chromatography were described earlier[1,2]. The chromatograms were satisfactory until certain days in April, when the normally pink and purple spots given by indoles with *p*-dimethylaminobenzaldehyde showed a diminished colour intensity and brown discoloration. The colours became so weak in May that indole spots could not be seen with certainty. Unlike the indoles, the phenolic acids gave colours which were normal immediately after spraying with diazotized sulphanilic acid, but which faded and were discoloured afterwards to an increasing extent. No improvement was obtained when the components of the chromatographic solvents were purified extensively.

The occurrence of chromatographic difficulties appeared to coincide with an increased level of atmospheric contaminants. The eye-irritating haze known as 'smog', develops frequently in the Los Angeles area where topography and meteorological conditions favour the formation of a large stagnant air mass and the accumulation of fumes from numerous industries and other sources. 'Smog' contains ozone, organic peroxides, nitrogen oxides and other components[3]. The 'smog' level was low early in 1958 because of unusually heavy rains, but became noticeable in April and marked in May; an atmospheric ozone content of 0·35 parts per million was reported in Pasadena on May 15.

Several other features suggested that oxidative atmospheric contaminants were responsible for the destruction of indole spots on chromatograms. Ozone has been used preparatively to rupture the pyrrole ring of indole compounds[4]. The instability of ozone and organic peroxides in alkaline media is well known; on the other hand, ozonization is frequently carried out in acetic acid. These properties may explain why one-dimensional chromatograms developed in *iso*propyl alcohol/ammonia/water (8 : 1 : 1) furnished indole spots with almost normal colours with *p*-dimethylaminobenzaldehyde at a time when those run in benzene/propionic acid/water (100 : 70 : 5) did not.

A pertinent counterpart to these observations was provided by a report concerning the adverse effects of 'smog' on the response of plants to indoleacetic acid[5]; the 'smog' was eliminated by filtering the air through charcoal[6]. This approach also afforded a solution to the present problem. Two sets of two-dimensional chromatograms were prepared from four different urine extracts. One set was dried in the hood as usual; *p*-dimethylaminobenzaldehyde revealed faint brown (instead of blue) spots of only 5-hydroxyindoleacetic acid. The second set was dried in empty chromatography jars, after each solvent and after spraying, by a current of air which had passed through a 2-l. aspirator bottle filled with 8–12 mesh activated charcoal; 14 indole spots with normal colours were observed on this set of chromatograms. A charcoal unit large enough to ensure a 'smog'-free room is being designed.

The formation of 'smog' is a problem of increasing importance in densely populated and heavily industrialized cities. These findings, therefore, may be of interest to investigators working in such areas with small amounts of compounds or biological systems which are sensitive to the action of atmospheric contaminants.

Inhibitory Action of Ethyl Mercaptan on Intracellular Tubercle Bacilli

We have previously described the anti-tuberculous activity in mice of ethyl mercaptan and its derivatives[1,2]. The marked activity which was observed did not seem to correspond with the slight bacteriostatic action of ethyl mercaptan against *Mycobacterium tuberculosis in vitro*. Since the bacilli in tuberculosis are intracellular, we decided to test the effect of ethyl mercaptan against bacilli so located. For this purpose we used the method described by Suter[3] in which tubercle bacilli are grown *in vitro* within monocytes derived from peritoneal exudates of normal guinea pigs. Because of the high volatility of ethyl mercaptan it was necessary to modify Suter's method of incubating the cover-slips on which the monocytes and bacteria were attached. The tubes containing the cover-slips were sealed by heat before they were incubated, at an angle of 30° from the vertical, without rotation. This modification still allowed good growth of the bacteria and isoniazid was highly effective (Table 1).

Four cover-slip preparations from each treatment were stained at intervals of 1, 3, 5 and 7 days and 200 monocytes were examined on each slide and classified as containing 0, 1–10, 11–20, and more than 20 bacteria respectively. The activity of an inhibitory compound can be seen most conveniently from the percentage of cells containing more than 20 bacteria in the 7-day cultures.

Ethyl mercaptan was inhibitory at concentrations of the order of 10 μgm./ml., methyl mercaptan was ineffective; indeed it partially antagonized the effect of ethyl mercaptan. This is in accordance with our observations in mice[2]. The specificity of this effect was demonstrated by the failure of ethyl mercaptan to inhibit the intracellular growth of a strain of bacilli which had been made resistant to treatment with thiol esters in mice[2] (Table 1). Several potential metabolites of ethyl mercaptan, including methyl ethyl sulphide, methyl ethyl sulphone, β-hydroxyethyl methyl sulphide and β-hydroxyethyl methylsulphone were inactive, whereas the diethyl disulphide was active.

Table 1

Treatment or conditions of growth	Percentage of monocytes containing more than 20 bacteria at 7 days
Open tubes	86
Sealed tubes	97
Sealed tubes with isoniazid 0·1 μgm./ml.	25
Ethyl mercaptan 100 μgm./ml.	9
Ethyl mercaptan 10 μgm./ml.	18
Ethyl mercaptan 1 μgm./ml.	35
Untreated controls	35
Antagonism	
Ethyl mercaptan 100 μgm./ml.	12
Methyl mercaptan 100 μgm./ml.	40
Ethyl mercaptan 100 μgm./ml. + methyl mercaptan 100 μgm./ml.	19
Untreated controls	34
Strain resistant to ethyl thiol esters (ref. 2)	
Ethyl mercaptan 100 μgm./ml.	83
Isoniazid 1 μgm./ml.	5
Untreated controls	80
Normal sensitive strains	
Ethyl mercaptan 100 μgm./ml.	25
Untreated controls	68
Human monocytes	
Ethyl mercaptan 100 μgm./ml.	10
Untreated controls	63

The inhibitory action of ethyl mercaptan was also demonstrated using human monocytes obtained from a patient suffering from monocytic leukæmia (Table 1).

A Simple Method for making Starch-gel Electrophoretic Strips Transparent

Starch-gel electrophoresis, as introduced by Smithies[1], has proved superior to both free and filter-paper electrophoresis for separating protein mixtures[2–6]. However, the opacity of the strips excludes the possibility of direct quantitative evaluation of separated proteins, though this is possible with the other two electrophoretic methods. This problem was successfully solved recently by Fine and Waszczenko[7], who prepared starch-gel suitable for direct quantitative evaluation by transmission photometry. A simpler and quicker method for obtaining transparency of the strips is presented here.

At the end of the run, the standard $\frac{1}{4}$-in. thick starch-gel strip is transferred into a $\frac{3}{16}$-in. deep slicer of the type described by Smithies[1]. This is then covered with a $\frac{1}{16}$-in. deep slicer, and the cutting is performed lengthwise between these two. In this way the upper portion of the strip is removed and then discarded. The rest of the strip is transferred into a $\frac{1}{8}$-in. deep slicer, then covered and sliced as above except that this slice is transferred to the staining dish. Similarly, another slice is cut in a $\frac{1}{16}$-in. deep slicer and is also transferred to the staining dish. In this way two $\frac{1}{16}$-in. strips of the central portion of the original strip are obtained.

Staining the strips is carried out in a saturated solution of buffalo black in a methyl alcohol/water/acetic acid (50 : 50 : 1) solution for a period of 2 min. The same solution, but without the dye, is used for removal of the background stain, which occurs after the strips have been left in the washing solution for 12–16 hr. Strips are then transferred to a tray containing a 10 per cent solution of acetic acid and boiled for 30 sec., after which the whole is cooled to room temperature. Such a procedure renders stained strips transparent. Strips should not be removed from the acetic acid solution before cooling since they are very fragile. Transparency of the strips treated thus is greater than that of freshly formed gels, while their consistency is of the same order.

It is worth mentioning that certain protein fractions which are present in minute amounts are more readily visible after the strips are made transparent.

In order to evaluate these strips photometrically, they are transferred into a $\frac{1}{16}$-in. deep slicer and covered by a 'Plexiglass' strip. Care should be taken not to trap any air bubbles below or above the strip. This can be achieved by carefully laying the strip on the slicer and delivering a sufficient amount of acetic acid solution around and on the top of the starch-gel strip prior to its covering.

If one wishes to preserve starch-gel strips for future reference, one should transfer them back to the methyl alcohol/water/acetic acid solution, in which they solidify after resuming their original opacity.

I wish to acknowledge the help and assistance of Dr. O. Smithies in introducing the starch-gel electrophoresis method in this laboratory.

Thermal Decomposition of Antibiotics

Previous work on the thermal decomposition of the tetracycline series of antibiotics in which aureomycin, terramycin and tetracycline were studied[1] has been extended to include erythromycin, leucomycin base, oleandomycin phosphate and carbomycin.

The thermograms were obtained by use of an automatic recording thermobalance[2], using the same procedure as before[1]. The antibiotics were obtained as commercial samples and were not further purified before pyrolysis.

The thermograms of the four antibiotics are given in Fig. 1. Although a detailed analysis of the decomposition mechanism is difficult to make, the loss of bound water is readily detected. Any further interpretation of the decomposition process is difficult to do because of the complex structure of the antibiotics and also because the pyrolysis was carried out in air.

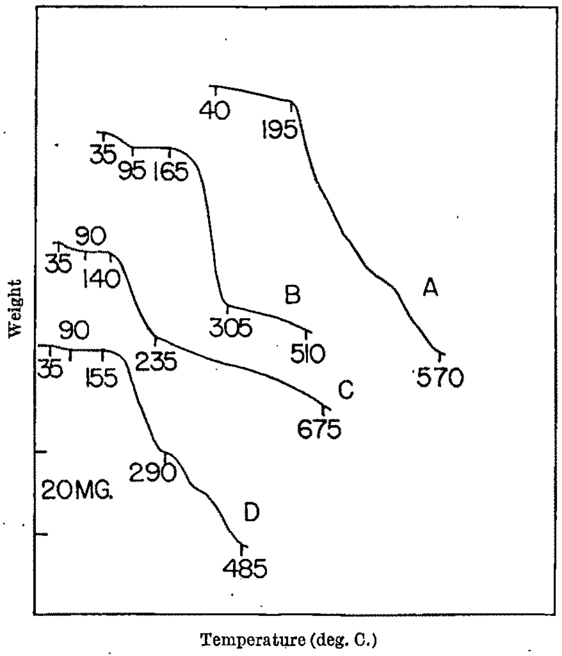

Fig. 1. Thermal decomposition of antibiotics: *A*, carbomycin; *B*, erythromycin; *C*, oleandomycin phosphate; *D*, leucomycin base

Erythromycin. The first loss in weight for this antibiotic was observed at about 35° C. After this initial loss in weight, a horizontal weight-level was found extending from 95° to 165° C. This first loss in weight is thought to be due to the evolution of loosely bound water. Previous studies have shown that this water is completely lost at 55° C. under reduced pressures[3]. Beyond 165° C. the antibiotic decomposed rapidly, leaving a small amount of carbonaceous matter (less than 10 per cent) in the thermobalance pan at 510° C.

Carbomycin. The antibiotic lost weight continuously from 40° to 570° C. Starting at 40° C., the loss in weight was quite slow until 195° C. was reached, when it began to decompose rapidly. As with erythromycin, some carbonaceous matter remained at 570° C.

Oleandomycin phosphate. The first loss in weight was observed at 35° C. After this initial loss, a nearly horizontal weight-level was observed from 90° to about 145° C. Beyond 145° C. the antibiotic decomposed rapidly, giving a break in the curve at 235° C., then further decomposition up to 675° C. Since this was a phosphate salt, the phosphate was left behind with the unoxidized carbonaceous matter.

Leucomycin base. After an initial loss in weight beginning at 35° C., a horizontal weight-level was observed from 90° to 155° C. Beyond 155° C., the antibiotic decomposed rapidly, giving a break in the curve at 290°. Further decomposition then occurred above 290° C. to give a small amount of carbonaceous matter at 485° C.

Separation and Determination of the Dissociation Constants of Chelidonine and Protopine by Paper Chromatography

IN connexion with the chromatographic separation of alkaloids of *Chelidonium maius* L.[1], I found alkaloids giving rather big spots with a tendency to form tails. This is connected, among other things, with the dissociation constant (K_B), the value of which influences the course of the chromatographic process, organic electrolytes having different values of K_B in the water phase and the organic phase of dissociation.

By the use of buffer solutions and a proper choice of *p*H, the degree of dissociation can be regulated and thus the distribution ratio. This also affects the shape and the rate of migration of bands.

Attempts were made at separating chelidonine and protopine by means of buffered paper. The application of the methods of Waksmundzki *et al.*[3,4], who use a slightly moistened buffered paper, reduced the duration of the chromatographic process significantly. The dissociation constants of the alkaloids which were also calculated from formulæ[5] could also be determined. Moistened paper is slightly adsorptive, so continuous counter-current extraction takes place. Whatman No. 4 paper and the apparatus described by Waksmundzki and Soczewiński[4] were used. The mobile phase was chloroform, which is a good solvent for the two alkaloids. Its low viscosity considerably shortened the time of analysis. The chromatogram was developed over 15 cm.

The initial attempts, using moistened but unbuffered paper, gave negative results: the alkaloids migrated with the solvent front ($R_F = 1$).

In buffering the paper seven liquids in the *p*H range 1–6·45 were prepared. The values were checked with a *p*H-meter.

In order to determine the optimal value of the 'moistening index',

$$W = \left(\frac{\text{weight of moistened paper}}{\text{weight of dry paper}}\right)$$

the studies were carried out on paper buffered at *p*H 2. The effect of moistening the paper on the behaviour of the alkaloids and the duration of the chromatographic process were observed. The results are shown in Table 1.

It can be seen from Table 1 that 1·5 is the best value of W_z since the separation was obtained in a

Table 1. EFFECT OF MOISTENING THE PAPER ON THE R_F VALUE AND DURATION OF THE CHROMATOGRAPHIC PROCESS

Alkaloid	R_F with W_z = 1	1·5	1·75
Chelidonine	0	0·53	0·57
Protopine	0	0	0
Time (hr.)	1	1	4

comparatively short time. This value was used in further work.

Table 2 illustrates the dependence of R_F on the pH of the aqueous phase.

As appears from Table 2, acidification makes a good separation possible. The spots were distinct after development with Dragendorff's reagent, and did not form tails.

From Fig. 1 it can be seen that the two alkaloids have different dissociation constants. Assuming that the best separation is obtained when the arithmetical mean of the two values is ½, the optimal value for pH will be 2·9–3·5. In this range protopine has moved from the start line and chelidonine has not reached the front (the mean R_F value is about 0·45).

The points marked (+) were obtained experimentally, whereas those marked (O) were calculated using the equation deduced by A. Waksmundzki and E. Soczewiński[5]:

$$R_F = \frac{kr}{kr + 1 + \dfrac{K_B}{[\mathrm{OH}^-]}}$$

where $[\mathrm{OH}^-]$ is the concentration of hydroxyl ions in the aqueous phase; k is the partition coefficient of the substance under examination between the organic phase and the water phase; r is the ratio of the volume of the organic phase to that of water; and K_B is the dissociation constant of the base in question.

The experimental results served to determine the dissociation constant of the alkaloids under examination. From the difference in weight between a moistened strip and one that had been chromatographed with chloroform, the weight of chloroform in a known part of the strip was calculated. This weight was converted to a volume, and hence a value of 1·86 was obtained for r.

In order to determine k, weighed portions of the alkaloid were dissolved in chloroform and shaken with an equal volume of water. The aqueous phase was titrated with 0·05 N hydrochloric acid and the amount of alkaloid calculated. These results were checked by weighing the residue of alkaloid after the solvent had been evaporated from the chloroform phase. k was found to be 23·4 for chelidonine and 29·5 for protopine.

Substitution of these values of k and r in equation (1) gave $3{\cdot}8 \times 10^{-11}$ and $9{\cdot}73 \times 10^{-9}$ as the dissociation constants of chelidonine and protopine respectively.

Table 2. DEPENDENCE OF R_F ON THE pH OF THE BUFFER

pH	R_F of chelidonine	R_F of protopine
1·00	0·04	—
1·75	0·22	—
2·20	0·53	0·0
3·50	0·94	0·13
4·60	0·98	0·63
5·68	0·99	0·93
6·45	1·00	0·98

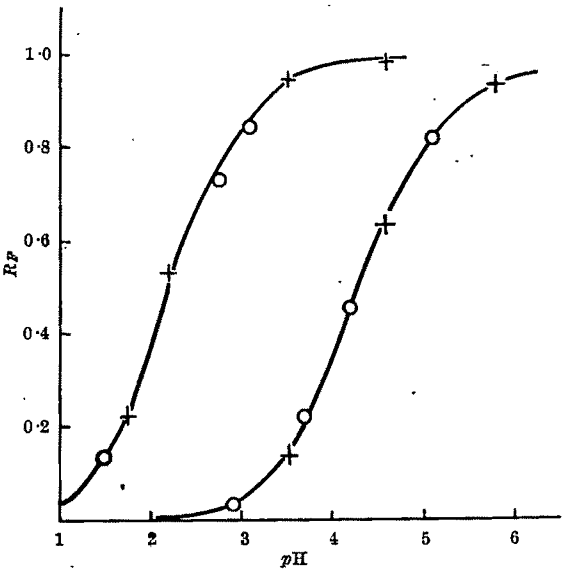

Fig. 1. Relation between R_F and pH for chelidonine and protopine. For key, see text

Thus the use of moistened, buffered paper permitted the separation of the substances under examination and the calculation of their dissociation constants. Because of the great differences in the partition coefficients of these alkaloids, a good separation is to be expected with Craig's countercurrent extraction method, using a buffer solution of pH 3·5 and chloroform.

Riboflavin in Yellow Semen

MOST specimens of bull semen are almost white, but during the course of unrelated studies[1] on spermatozoa it was observed that the semen from one particular bull was quite yellow. The colour was confined to the plasma fraction and ultra-violet light produced a green fluorescence similar to that emitted by riboflavin. Other reports[2-4] have since been noted which suggest that the yellow pigmentation of bull semen may be attributed to riboflavin, and recently eight bulls producing yellow semen have been located, thus permitting a more critical and extensive investigation. The production of yellow semen was characteristic of these bulls, which were located in scattered parts of Australia and New Zealand. All bulls producing yellow semen were of the Friesian breed, and six were the first, second or third generation descendants of one sire. The pigmentation apparently does not affect the fertility of the semen since the bulls were in use at artificial insemination centres and the spermatozoal concentration and morphology were normal.

Qualitative tests showed that the yellow pigment had the properties of riboflavin and confirmation was obtained by chromatography of ethanol extracts of the semen using 5 per cent disodium hydrogen phosphate, *n*-butanol/acetic acid/water (4 : 1 : 5) and methanol as solvents. Light blue spots, one corresponding to lumichrome, were also present and an unknown violet spot which ran well ahead of riboflavin in *n*-butanol/acetic acid/water but remained at the origin in 5 per cent disodium hydrogen phosphate.

Quantitative aspects were studied by estimating the riboflavin content of sixteen yellow ejaculates and nine control white ejaculates. In the estimations of riboflavin[5] by conversion to lumiflavin, the preliminary chloroform extract of yellow semen was also found to give a fluorescence. This was measured quantitatively and expressed as the amount of riboflavin which on irradiation in alkaline solution gave an equivalent fluorescence. The riboflavin (mean 18·9 μgm./ml., population standard deviation 6·0) and flavin-soluble chloroform (mean 19·1 μgm./ml., standard deviation 6·3) content of the yellow samples were each about forty times that of the colourless samples and sufficient to account for the pigmentation. Both first and second yellow ejaculates obtained at any one time from individual bulls had a high flavin content which showed little variation although different samples were collected at intervals over a period of several months. It is particularly interesting that the ratio of riboflavin to flavin soluble in chloroform remained fairly constant at unity. Neither niacin[5] nor thiamin[5] values differed greatly between the groups, and the fructose levels for fourteen yellow ejaculates (mean 458 mgm. per cent, standard deviation 86) were normal.

On standing for several hours the yellow colour of the semen fades. Analysis demonstrated that this was due to the breakdown of riboflavin by sunlight rather than any metabolic activity of the spermatozoa. Chromatography showed that the lumichrome content increases at the expense of riboflavin. Ribitol, which might be expected to result from the photolysis of riboflavin, is not utilized by bull spermatozoa since the addition of 1 mgm. to 1 ml. of washed cells failed to increase the uptake of oxygen.

The results clearly establish that the yellow coloration of bull ejaculates is due to riboflavin. Yet other flavins, particularly one soluble in chloroform, are present in high concentrations even when the most rigorous precautions are taken to exclude light during collection and handling of the semen.

Blood riboflavin levels were not elevated, and other bulls under the same conditions of husbandry produced normal semen; it is thus unlikely that the colour of the semen is influenced by diet. The evidence strongly suggests that the characteristic is hereditary and that it behaves as a Mendelian dominant. In view of the blood analysis, the general tissues of these bulls are unlikely to synthesize the flavins. It seems more likely that we may be dealing with a genetic mutation in which the accessory organs, probably the seminal vesicles, have the specific ability to make, or more likely to concentrate, riboflavin and other flavins.

When added to white ejaculates at a concentration of 20 μgm./ml., riboflavin usually halved the uptake of oxygen and decreased the longevity of the spermatozoa. The possibility that this is due to the formation of hydrogen peroxide is being investigated. full report of this work will appear elsewhere.

Thanks are due to Prof. C. W. Emmens for h interest and advice, to Mauri Bros. and Thompson fc the use of laboratory facilities and to Roche Produc Pty., Ltd., for gifts of chemicals. We are also indebte to the Camden Park Estate, Mr. B. Doyle, Mr. Martin, Mr. R. Hayman and Dr. James for makin bull semen available or for checking its colour.

Dissociation of Serological Complexes of Ovalbumin and Hæmoglobin using Aqueous Carbon Dioxide

In connexion with work on the fractionation o proteins by specific immunochemical methods, th dissociation of antigen–antibody complexes has bee studied. The aim was to effect this dissociation b less drastic methods than those used hitherto fo obtaining antibody[1] and if possible to isolate antige free from antibody.

Mitz[2] showed that carbon dioxide increased th solubility of some proteins in salt-free water, and thi work prompted our attempt to dissociate serologica complexes with the same reagent. The procedure me with some success when applied to ovalbumin/rabbi antibody and to horse hæmoglobin/rabbit antibod systems.

Our first experiments involved the specific precipitate of ovalbumin and its antiserum prepared in th rabbit by a short term (4 weeks) immunizing procedure. The precipitate, washed free of salt, wa soluble in aqueous carbon dioxide (0·035 *M*; *p*H 5·0 and partial dissociation of the complex was show by sedimentation analysis; two boundaries (Fig. 1*a* resolved with $S_{20,w} \simeq 5$ and 13. The slower boundar corresponded to immune globulin, the unsuppresse 'primary charge effect'[3] being mainly responsible fo the low S_{20}. Control runs using rabbit γ_2-globulin showed that the S_{20} was reduced from 6·56 S. (*I* 0·1 veronal buffer *p*H 8·6) to 5·1 S. in aqueous carbo dioxide. Different batches of precipitate produce similar sedimentation patterns although the S_{20} value were subject to some fluctuations. The pattern were not markedly altered by variation in the age o the complex, or in the temperature (3–36° C.) or ag (2 hr. to 7 days) of the solution. In contrast, significant shifts in the equilibrium, resulting in a smalle globulin release, an increase in S_{20} of the comple and finally in precipitation, were observed when th carbon dioxide concentration was decreased t 0·01 *M* or sodium chloride was added to a concentration of about 9×10^{-3} *M*.

Free antibody (15–25 per cent) was isolated fro this system by differential ultracentrifugation in

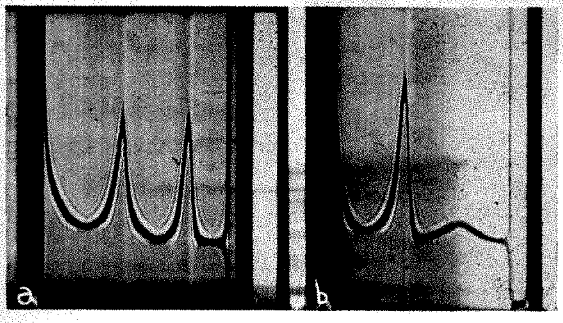

Fig. 1. Schlieren photographs from the 'Spinco' Model *E* ultracentrifuge. Solvent: aqueous carbon dioxide (0·035 *M*, *p*H 5·0). Speed 59,780 rev./min. Sedimentation from right to left. (*a*) Partially dissociated ovalbumin – rabbit antiserum complex. Initial *C* = 1·0 per cent w/v. Exposure after 34 min. at full speed. (*b*) Dissociated horse hæmoglobin – rabbit antiserum complex. Initial *C* = 0·85 per cent w/v. Exposure after 101 min. at full speed

bucket rotor ('Spinco' *SW* 39) at 150,000*g* for 6 hr. Attempts to increase the yield by reworking the deposits were increasingly penalized by the formation of complexes with reduced S_{20} values as more antibody was removed.

The isolated globulin showed no evidence of heterogeneity on sedimentation and electrophoresis, and the absence of antigen was confirmed by observation on antibody dissociated from a complex of ovalbumin labelled with fluorescein. In veronal buffer (*I* 0·1, *p*H 8·6) it had an S_{20} (6·56 S.; $C = 0·3$ per cent) and an electrophoretic mobility ($-1·2 \times 10^{-5}$ cm.^{2} V.$^{-1}$ sec.$^{-1}$) similar to those for normal rabbit γ_2-globulin. Its serological properties appeared to be unimpaired; at least 90 per cent was precipitable by ovalbumin and the characteristics of the precipitin curve were similar to those obtained for the original antiserum.

The work was extended to a specific precipitate of horse hæmoglobin and its rabbit antiserum prepared by a short-term immunization[5]. Once more the precipitate was readily soluble in aqueous carbon dioxide (0·035 *M*), but here a complete dissociation of complex occurred.

Sedimentation analysis of this solution (Fig. 1*b*) showed a major boundary corresponding with free immune globulin and a minor boundary ($S_{20} \simeq 2$) which corresponded with horse hæmoglobin when run under these conditions. The absorption of light (546 mμ) was clearly associated with the minor boundary, but of greater significance was the uniformity of absorption over the major boundary, which indicated that complete dissociation of the complex had been achieved. No hæmoglobin complex appears to exist at *p*H 5·0 in aqueous carbon dioxide, whereas the existence of complexes in solution was demonstrated by sedimentation analysis of specific precipitate dissolved in veronal buffer (*I* 0·001, *p*H 8·3). Here a broad boundary ($S_{20} \simeq 29$) and a trace of globulin were observed but no peak corresponding with hæmoglobin. The light absorption by hæmoglobin was only detectable in the main peak and thus the hæmoglobin was presumably fully complexed.

A cation-exchange cellulose (*CM*)[6] was used instead of the ultracentrifuge to separate the two components of this system, and antibody was isolated in good yield. Aqueous carbon dioxide (0·035 *M*) was used to equilibrate the cellulose column, for the application of the complex and in the development of the chromatogram. Afterwards, antibody was eluted with phosphate-saline buffer (*I* 0·044, *p*H 7·1) in 85 per cent yield while hæmoglobin remained strongly adsorbed. The eluted protein was identical with γ-globulin on paper electrophoresis and in sedimentation analysis, and the absence of hæmoglobin was confirmed by measurements of light at 410 mμ. The product contained at least 55 per cent precipitable antibody despite the susceptibility of the original hæmoglobin system to the formation of soluble complexes. Furthermore, 75 per cent of the added antigen was found in the equivalence zone precipitate in contrast to the low hæmoglobin recoveries (about 18 per cent) in precipitates from the original antiserum.

The work has been extended to the following systems: a polysaccharide[7] from *Shigella dysenteriae*/rabbit antiserum to the homologous *O* somatic antigen, horse serum albumin/rabbit antiserum to horse serum, and diphtheria toxin/horse antitoxin. These specific precipitates dissolved in aqueous carbon dioxide and preliminary examination in the ultracentrifuge indicated that some γ-globulin was released.

The solution and partial dissociation of the ovalbumin complex is not specific to aqueous carbon dioxide. It can be effected to varying extent with many organic and inorganic acids at *p*H 5, and even in the *p*H range 7–8, providing the ionic strength of the solution is low. At present, however, aqueous carbon dioxide appears to be the most advantageous method, and one of the mildest yet reported for dissociating some serological complexes. A full account of this work will be given elsewhere.

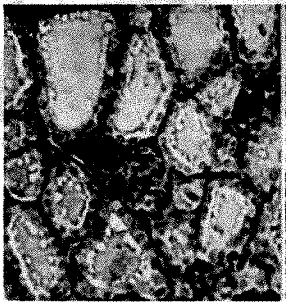
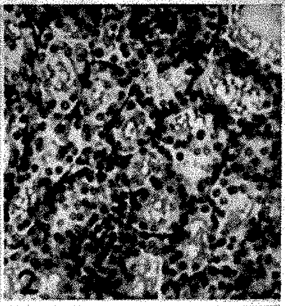
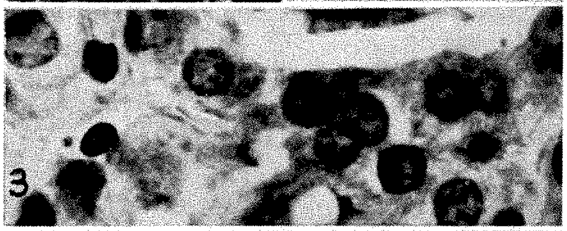
Effect of Benzene on Rat Thyroid

IN previous investigations on the anterior pituitary of rats intoxicated with benzene we found histochemical changes suggesting an increased hormone secretion from both the acidophil cells and the beta cells[1]. Since the beta cells are believed to be concerned in the rat with the secretion of thyrotrophic hormone and are therefore also called thyrotrophs[2,3], it seemed of interest to determine whether the hyperfunction of the pituitary beta cells is paralleled by cytological signs of augmented activity in their target gland, the thyroid.

Fourteen male Wistar rats, weighing on an average 260 gm., were given daily subcutaneous injections of 1 ml./kgm. body-weight of a solution containing equal parts (v/v) of benzene and olive oil. Four animals receiving only olive oil served as controls. All rats were killed by gas on the morning following the twenty-second injection. The thyroids were fixed in Helly's fluid and embedded in paraffin.







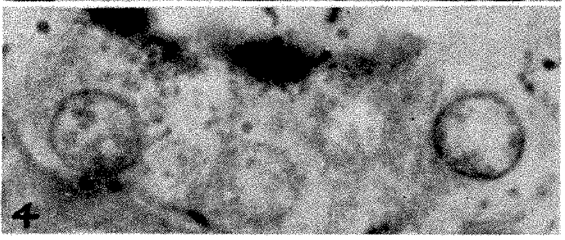


Fig. 1. Normal rat thyroid (hæmatoxylin–eosin). (× 160)

Fig. 2. Treated rat thyroid (hæmatoxylin–eosin). (× 160)

Fig. 3. Showing the cytoplasmic chromidial substance in treated rat thyroid (toluidine blue). (× 1,200)

Fig. 4. Colloid droplets at the apical pole of follicular cells in treated rat thyroid (periodic acid–Schiff). (× 2,000)

Sections were cut at 5μ thickness and stained by one of the following techniques : hæmatoxylin–eosin, methyl green–pyronin, Feulgen reaction, toluidine blue, periodic acid–Schiff reagent.

A series of morphological alterations has been consistently found in all the thyroids of the rats intoxicated with benzene. Most follicles show a much smaller size than those of control rats (Figs. 1 and 2). The follicular cells are high and columnar in shape, their nuclei appear vesicular and weakly stained by Feulgen, and the cytoplasm contains an increased quantity of chromidial substance (ergastoplasm) (Fig. 3), which is apparently related to the capacity of the thyroid cells to synthesize proteins[4,5]. Variable numbers of colloid droplets are clearly demonstrated in the cytoplasm of the follicular cells with the periodic acid–Schiff reaction : they are extremely abundant in some cells and very infrequent in others, while in some cells colloid droplets can be seen only at the apical or at the basal pole (Fig. 4). The colloid accumulated in the lumen of the follicles shows more numerous and larger vacuoles than in control rats, and is generally less intensely stainable (Figs. 1 and 2). Interspersed among the follicular cells lie many parafollicular cells, containing a scanty amount of chromidial substance (Fig. 3) and only few colloid droplets. The interfollicular cells are also abundant (Fig. 2).

Our findings resemble very closely the structural changes which occur in the thyroid when the gland is stimulated[4,5]. Therefore, it seems that under our experimental conditions benzene intoxication causes an increase in the secretory activity of the rat thyroid.

Separation and Isolation of Fractions of Rabbit Gamma-Globulin containing the Antibody and Antigenic Combining Sites

SOME years ago[1] the digestion of rabbit anti-ovalbumin with papain powder was investigated, and it was found that a fragment could be obtained which would no longer form a precipitate with ovalbumin but which would specifically inhibit the precipitation of ovalbumin with undigested antiserum. This fragment, which presumably contained an antibody-combining site, was believed to have a molecular weight of 40–50,000, or about one-quarter that of the original γ-globulin. Earlier, Peterman[2] had shown by ultracentrifuge studies that digestion of human γ-globulin with crude bromelin and papain produced fragments of one-half to one-quarter the size of the original molecule.

In both cases large amounts of crude enzymes were used (50–100 per cent of the weight of the substrate) and consequently investigation of the digestion products was confused by the presence of substantial amounts of non-γ-globulin protein. We therefore decided to repeat the digestion of rabbit γ-globulin with papain, this time using the crystalline enzyme, which can now be prepared[3] easily, and in much lower enzyme-substrate ratios. The conditions of digestion were : 100 mgm. rabbit γ-globulin and 1 mgm. crystalline mercury papain in 3 ml. buffer, *p*H 7·0 (0·1 *M* potassium phosphate, 0·01 *M* cysteine, 0·002 *M* sodium ethylenediamine tetraacetate). This solution was incubated for 16 hr. at 37° C. The digest was dialysed with vigorous stirring and several changes of outer fluid at 2° C. More than 90 per cent of the protein was retained in the dialysis sack and

when this material was examined in the ultracentrifuge it showed only a single component with $S_{20,w} = 3{\cdot}5$. No effective resolution could be obtained by electrophoresis but on chromatography on carboxymethyl cellulose[4], using gradient elution with an acetate buffer at *p*H 5·5, three components were separated in approximately equal amounts (Fig. 1). Preliminary estimation of the molecular weights of these components by Dr. P. A. Charlwood using the Archibald procedure[5] gave values of 55–60,000. It would thus appear that the rabbit γ-globulin is split into thirds with very little production of small fragments.

If the γ-globulin contained anti-ovalbumin, anti-bovine serum albumin (B.S.A.) or anti-human serum albumin (H.S.A.) fractions I and II specifically inhibited the combination of the same antigen and undigested antiserum, but had no activity in a heterologous system. Thus a digest of anti-human serum albumin γ-globulin will inhibit the human serum albumin – anti-human serum albumin reaction but has no influence on the bovine serum albumin – anti-bovine serum albumin system (Fig. 2). If the γ-globulin contained anti-pneumococcus polysaccharide type 3 or did not contain any known antibody then these fractions had no activity. The negative result with the polysaccharide antibody may imply a basically different structure to anti-protein antibodies but it may also be a reflexion of the quite different physical character of the antigen and the type of precipitate formed. It is possible that a different technique would show that fractions I and III from an anti-polysaccharide digest also retained the power to combine specifically with the antigen.

Fraction III showed no power to combine with the homologous antigen whatever type of antibody was present in the digest. However, when the antigenic activity of the fraction was tested with a goat anti-rabbit γ-globulin serum it was found that this fraction would precipitate most and probably all the anti-γ-globulin antibody. Fractions I and II neither formed a precipitate with the anti-γ-globulin serum nor did they inhibit precipitation of whole rabbit γ-globulin with the goat anti-serum. Fraction III has a minimum solubility between *p*H 5 and 7·5 and may be readily crystallized and recrystallized by dialysis of an alkaline or acid solution against 0·1 *M* phosphate buffer *p*H 6·5. The crystals (Fig. 3) are diamond-shaped birefringent plates, well formed but thin and easily broken, so that fragments seem always to be present. This ease of crystallization is surprising as whole rabbit γ-globulin has never been crystallized.

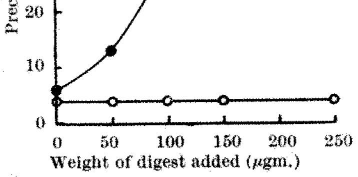

Fig. 2. Inhibition of precipitation of human serum albumin and rabbit anti-human serum albumin by a papain digest of rabbit γ-globulin containing anti-human serum albumin. ●, Precipitation time of human serum albumin – anti-human serum albumin; ○, precipitation time of bovine serum albumin – anti-bovine serum albumin

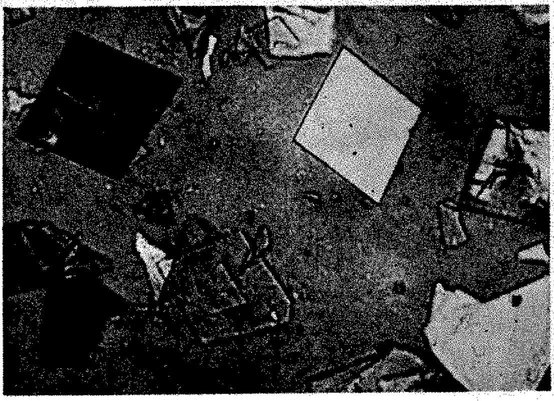

Fig. 3. Crystals of fraction III. Polarized light. (× 50)

These results suggest that the γ-globulin molecule may be made up of three parts; one of these (my crystalline fraction III) is identical in all γ-globulins molecules and is responsible for the common antigenic specificity of γ-globulins observed by Treffers and Heidelberger (see Treffers[6]). The other two parts (fractions I and III) presumably contain the antibody-combining centres, and are also responsible for the physical heterogeneity of γ-globulins; these parts may be expected to vary from molecule to molecule. This suggested structure of an identical section in all molecules of γ-globulins and two variable sections which contain the antibody-combining sites is very similar to the picture drawn by Pauling[7] in 1940. At that time he suggested that the flexibility of the variable sections might be a result of high proline content, but a rough comparison of the amino-acid composition of the three fractions by paper chromatography showed the proline content of each to be of the same order. We have no information on the essential feature of Pauling's theory of antibody formation, namely, that the antibody-combining sites are formed by refolding of a polypeptide chain with an identical amino-acid sequence. The N-terminal pentapeptide is the same in several rabbit antibodies[8,9] but it remains to be shown that this identity of sequence persists through the peptide chain, including the section containing the antibody-combining site.

Fuller details of this work will be published elsewhere.

I wish to thank Dr. P. A. Charlwood for studies of the three fractions with the ultracentrifuge, Dr. J. H. Humphrey for the gift of goat anti-rabbit γ-globulin serum, Mrs. O. Kennard for advice on crystallization techniques and Miss H. Morgan for her technical assistance.

Heat, Salt and Hormones in Panting and Sweating Animals

IN hot climates sweating or panting to provide evaporative cooling are required for the survival of mammals. The loss of extracellular water is linked with cell water exchanges, renal water-saving, adjustments of salt excretion and hormone production.

Within 30 min. of the induction of sweating in normally hydrated man (7 subjects) at 41° C. there was reduction of urine flow to rates below 0·3 ml./min. and reduction in the rates of excretion of sodium below 20 μequiv./min. This was associated with a fall in the sodium/potassium in the urine (Fig. 1*A*). During a period of sweating at the rate of 430–500 ml./hr. conservation of sodium and water ran parallel, as a renal compensation for salt lost in sweat[1]. Ten times the resting amount of aldosterone-like activity appeared in the urine during heating, and this probably accounts for the sodium retention[2] (see also Weiner, J. S., 1st Bioclimatological Cong., Int. Soc. Bioclimatology and Biometeorology, Vienna, September 23–27, 1957; Abstract).

When sheep were studied in a similar hot environment a different pattern emerged. Romney sheep exposed to 41° C. for 4 hr. showed a prompt fall of urine flow on heating. As the respiratory-rate increased for evaporative cooling there was a progressive increase in excretion of sodium and the ratio sodium/potassium rose (Fig. 2). No aldosterone activity was detected in the urine. When sheep were later provided with water to replace that evaporated, the excretion of sodium ceased and there was reversion to a low ratio sodium/potassium in the urine (Fig. 1*B*). Excretion of potassium declined regularly from 200 to 50 μequiv./min. during the period of heating while sodium moved in the opposite direction. Sheep excrete sodium by day more than by night, but the diurnal excretion of sodium is not reversed by heating. The elimination of sodium is presumably a homœostatic compensation for the distillation of water from the respiratory tract. Sheep appear to have no effective sweat glands and are not known to lose electrolytes through the skin during evaporative cooling. Merino sheep were more variable in their responses than Romneys, but followed the same course.

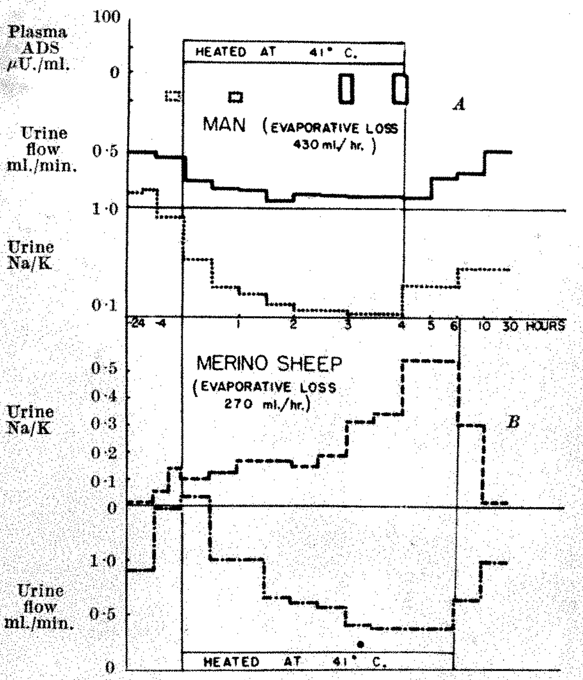

Fig. 1. *A*. Effect of heating at 41° C. on urinary flow and the ratio sodium/potassium in man. The urine flow reached 0·20 ml./min. before antidiuretic substance (ADS) appeared in the plasma. Sodium excretion fell during heating and sweating. *B*, In Merino sheep urinary flow fell on heating but the ratio sodium/potassium and excretion of sodium increased. There was a reversal of the ratio sodium/potassium as cooling took place

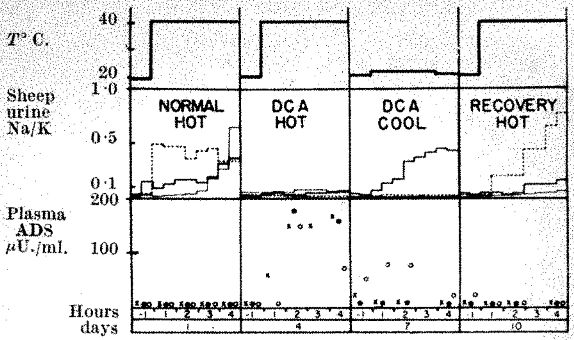

Fig. 2. Romney sheep (3) heated for 4 hr. at 41° C. in winter. No antidiuretic substance (ADS) appeared initially, but large amounts were released into the plasma after injections of deoxycortone (DCA) (0·15 mgm./kgm.). There was a low sodium excretion. Ten days later sodium was excreted during heating, but there was no production of antidiuretic substance

Winter exposure to the standard heat stimulus in both man and sheep led to low rates of flow of concentrated urine (0·1–0·3 ml./min.) without the liberation of measurable quantities of antidiuretic substance into the plasma[3–5]. During summer, antidiuretic substance appeared after 2–4 hr. heating at 41° C. The possibility that salt-active adrenal steroids might regulate the transfer of water and thus the release of antidiuretic substance was tested by exposing three Romney ewes to the standard hot environment in winter, when no antidiuretic substance normally appeared. The ewes were then injected intramuscularly with 15–20 mgm. of deoxycortone and heated for 4 hr. (Fig. 2). Little urinary sodium was excreted but antidiuretic substance appeared in the plasma on heating. As the effects of the hormone wore off the amount of antidiuretic substance appearing at 41° C. was reduced and after 10 days there was virtually no residual activity. In ten Merino sheep it was necessary to heat for 4 hr. at 44° C. to induce a release of antidiuretic substance in summer. When deoxycortone was injected into Merinos the release of antidiuretic substance persisted longer than in Romneys. Winter production of antidiuretic substance in the heat was achieved by injection of this salt-active hormone in both breeds.

In seeking the mechanism of this action of deoxycortone, estimates were made of the plasma volume and extracellular volume of man and sheep subjected to heat[6]. During winter when no antidiuretic substance appeared in the plasma of four men there was no decrease in the *T*1824 space and less than 1 l. loss of thiocyanate space after 4 hr. heating with the loss of 2·5–3·5 kgm. of sweat. Sheep heated for 4–6 hr., with the loss of 1·0–2·0 kgm. of water by evaporation showed less than 10 per cent change in the plasma volume in winter when antidiuretic substance did not appear. In summer, or when deoxycortone was given, there was a reduction in plasma and interstitial volume during heating and antidiuretic substance was detected in the blood. In the monkey, Sweet *et al.*[7] report an increase of the inulin space on treatment with deoxycortone and in sheep during summer we have found a 25 per cent expansion of the thiocyanate space relative to winter. This would not prevent plasma concentration from occurring if cell permeability to water were affected by the deoxycortone.

It appears that there is a difference between the summer and winter availability of tissue water in both man and sheep. In winter, extracellular water may be mobilized from other sources but not so easily as in summer. Simulation of summer responses to water loss was achieved by injections of deoxycortone. On the other hand, sodium retention in man[8] and excretion of sodium in sheep during heating at any time of the year means that salt-active hormones cannot be effective during the period of heating in both animals. Yet sheep heated in winter mobilize fluid to replenish the plasma space, thus preventing the relative plasma concentration associated with the release of antidiuretic substances, while sodium continues to be excreted. The sodium-resorbing hormone appears, then, not to be the final answer to this problem.

Sodium excretion during heating is thus linked to the method of evaporative cooling. In man producing salt sweat, sodium is retained by the kidney, whereas in sheep, which pant, there is excretion of sodium. There is a seasonal change in the amount of replacement of extracellular water from other sources during heating. When plasma is concentrated, antidiuretic substance appears, and plasma concentration on heating can be induced by deoxycortone. Flow of urine may be reduced to 0·2 ml./min. without antidiuretic substance being detectable in the plasma.

Correlation between the Fat and the Protein Content of Human Milk

I HAVE undertaken a study of the chemical composition of mature human milk (excluding colostrum) in the Kivu region of the Belgian Congo. The analyses were done on 250 samples of all the milk secreted during 24 hr. by mothers belonging to the Bashi tribe. This ethnic group lives along the eastern shore of Lake Kivu (about long. 29° E. of Greenwich) in the Belgian Congo, between latitudes 2° 10′ S. and 2° 40′ S. at an altitude varying from 1,460 to 2,000 metres above sea-level. Their staple foods are beans, sweet potatoes and beer made from bananas. Demaeyer took the samples in his quantitative study of milk secretion.

I found the mean caloric value, the protein-, fat- and ash-content of the milk from African mothers in the Kivu to be lower, and its lactose-content to be higher (although no statistical analysis of the difference between the means was possible), than the corresponding averages calculated by Macy *et al.*[1] from most literature reports on the composition of human milk and dealing mainly with European and American women.

The observation that both the fat and the protein in human milk are lower here than in other regions with higher dietary standards led us to examine the relation between the fat- and the protein-content of the milk from the mothers here.

A very strong positive correlation was found between the 'protein' (total nitrogen × 5·12)-content and the fat-content of the milk ($n = 224$, $r = 0{\cdot}4426$, $P < 0{\cdot}001$).

This means that for this region a milk sample with a low fat-content tends to have also a low 'protein'-content, that the fat-content of the milk and the 'protein'-content of the milk rise together, and that a milk sample with a high fat-content tends to have at the same time a high 'protein'-content. As far as we know, this correlation has not been observed before in human milk, and we think that it would be important if some of the workers in this field would examine their results in this light, to see whether the same correlation is observed elsewhere, with mothers having a completely different diet. It cannot be calculated from the literature on the subject because only mean values for the various components are published and not the analyses of individual samples. This observation may help towards a better understanding of the relation between the diet of the mothers and the nutritive value of their milk, and perhaps even of the mechanism of the milk secretion in the mammary gland. Breirem[2], in his review of the literature on the relation between the nutritional value of cow's milk and the nutrition of the animal, reports that Møllgaard and Lund, Steensberg, Kay, Breirem and Saarinen have observed that deficiency of energy and/or protein in the diet of the cow will reduce both the fat- and protein-content of the milk. Janz *et al.*[3] report a similar observation made by Escudero and Pierangeli for human milk; these authors reported that mothers with a diet rich in proteins secreted milk with a high protein- and fat-content.

These reports give indirect circumstantial evidence for the existence of this positive correlation between the fat- and protein-content of milk observed so clearly in my work.

Effect of Various Natural Steroids on the Phagocytic Activity of the Reticulo-Endothelial System

It was initially observed by Nicol[1] that, following the administration of œstrogenic hormones, there was stimulation of the activity of phagocytic cells in the endometrium. This work was extended later to include both natural and synthetic œstrogens[2-4], and these findings indicated that in both male and female animals œstrogens possess a strong stimulating influence on the reticulo-endothelial system, which results in the appearance of large numbers of macrophages in the spleen, liver and lymph nodes, and the mobilization of these macrophages into the circulation. In the above researches, the trypan blue method was used to assess the activity of the reticulo-endothelial phagocytes. These results have since been confirmed by the carbon method, and it has been found that the strongest stimulants of the reticulo-endothelial system possess high œstrogenicity[5,6].

The following investigation was planned to ascertain the effect of various œstrogenic and non-œstrogenic natural steroids on the phagocytic activity of the reticulo-endothelial system.

The present experiments were carried out on 105 male white mice (*T.O.* Swiss strain) of 20–30 gm. body-weight. Five of the animals were used for assessing the effect of each compound on the phagocytic activity of the reticulo-endothelial system, each animal receiving one subcutaneous injection of 0·5 mgm. of each steroid in 0·05 ml. of arachis oil daily for six days. The phagocytic activity was then measured on the eighth day by the rate of disappearance of a known amount of carbon from the circulating blood[7], the procedure being as follows. Each animal was given one intravenous injection of carbon of particle size 250 A., the dose of the carbon being calculated on the basis of 16 mgm. per 100 gm. body-weight. Blood was then taken at short intervals during the first 60 min. following the injection, and the concentration of the carbon in each blood sample was measured by means of an absorptiometer. The logarithmic values of the absorptiometer readings lie along a straight line when plotted against time, and the slope of this line has been taken as the measure of total body phagocytic activity or the phagocytic index, which is denoted in the present communication by the symbol K.

Twenty-five of the animals were used as controls. Each received one subcutaneous injection of 0·05 ml. arachis oil daily for six days and then showed an average phagocytic index or K-value of 13 ± 2·4, the carbon completely disappearing from the blood in about 100 min.

Table 1 shows the K-values of the various natural steroids together with their relative standard deviations. These results show that the phagocytosis of particulate carbon may be modified by natural steroids. The œstrogenic steroids caused rapid removal of the carbon from the blood-stream due to stimulation of reticulo-endothelial activity. Progesterone caused very slight stimulation of the reticulo-endothelial phagocytes. Cortisone caused marked depression of phagocytic activity, thus providing further confirmation of our previous reports of experiments involving the method of *intravitam* staining with trypan blue[8]. Testosterone and cholesterol and the other steroids shown in Table 1 had little or no effect.

Table 1. EFFECT OF VARIOUS NATURAL STEROIDS ON THE PHAGOCYTIC ACTIVITY OF THE RETICULO-ENDOTHELIAL SYSTEM

Steroid used	Phagocytic index (K-value)
Œstradiol benzoate	81 ± 15
Equilin	77 ± 24
α-Ethinyl œstradiol	75 ± 8·9
Œstrone	65 ± 11
Equilenin	51 ± 8·2
Œstriol	47 ± 9·8
Progesterone	17 ± 2·5
Ethisterone	14 ± 1·7
Testosterone	13 ± 1·1
Cholesterol	11 ± 2·5
Lanosterol	11 ± 1·7
Ergosterol	10 ± 1·9
Androstalone	10 ± 1·3
Sitosterol	10 ± 1·1
Deoxycortone acetate	10 ± 2·2
Cortisone	7 ± 0·9
Control values for 25 animals	13 ± 2·4

It is thus evident that the phagocytic activity of the reticulo-endothelial system is modified by hormones, and that the steroids possessing the power of inducing œstrus also induce stimulation of macrophage activity. Œstradiol benzoate has been found to be the most powerful of the natural œstrogens and gives a phagocytic index or K-value of 81 ± 15, the carbon disappearing completely from the blood in about 15 min. compared with 100 min. in the controls; cortisone acetate was again the major depressant, the circulating blood not being clear of carbon for about 2 hr. after the injection.

We are indebted to Dr. W. J. Tindall, of Organon, Ltd., who kindly supplied the majority of the steroids.

We also gratefully acknowledge assistance from the Central Research Fund of the University of London.

Action of Beta Radiation on the *Proteus P*18 Bacillus

We have grown the *Proteus P*18 bacillus at 37° C. in an ordinary medium containing 20 per cent horse serum and varying amounts of radioactive phosphorus. With a dose of 4 μc. of phosphorus-32 per 100 ml. of medium the multiplication and microscopic appearance of the bacilli are scarcely altered. When the concentration of phosphorus-32 is raised to 8 μc. per 100 ml., growth is slowed down and a series of important morphological transformations can be observed.

Between 4 and 6 hr. after inoculation, besides the normal *Proteus* bacilli, filaments 20–80μ in length, that show rapid creeping movements, appear (Fig. 1*b*). After 6–8 hr., filaments with a globular formation at one end are observed (Fig. 1*c*); these move very fast, the globule foremost. After about 8–10 hr.

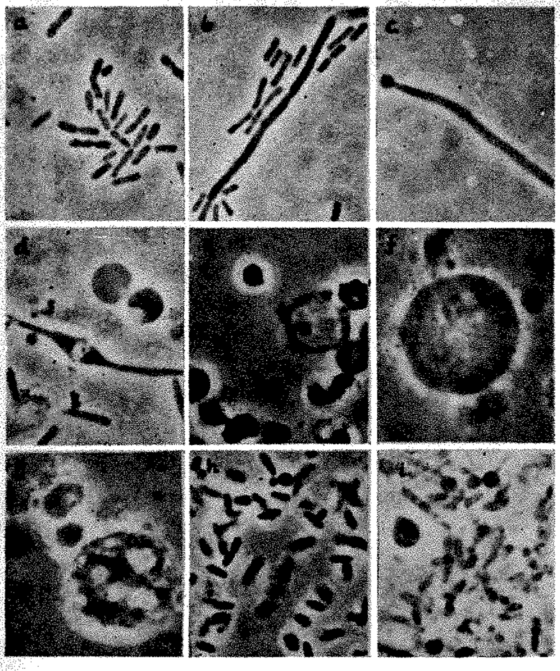

Fig. 1. Morphological changes of *Proteus P*18 under the influence of radiation from phosphorus-32. (*a*) Normal *Proteus* ; (1*b*–1*i*) see text

numerous dark globular elements 1–8μ in diameter are seen, as well as filaments with a median bulge (Fig. 1*d*). At the same time the normal bacilli become rare and the long filaments are very numerous. Certain globular formations have a small, very thin and spindly appendage in a spiral (Fig. 1*e*). After 15 hr. bright globular elements 8μ in diameter and small particles at the limit of visibility appear. After about 21 hr. the culture contains scarcely anything but dark or bright globular formations, 30–40μ in diameter, with black granulations or vacuoles (Figs. 1*f* and *g*). The small particles at the limit of visibility are very numerous ; but we were unable to photograph them. When the culture is prolonged, the globular formations become fewer and are replaced by a considerable number of small particles. After about 31 hr. there is a regression, and both short and long filaments and many thick rods appear ; some of the long filaments have a median bulge. Finally, after 48 hr., one finds normal bacilli again (Fig. 1*h*).

If a 21-hr. culture made in the presence of 8 μc. of phosphorus-32 and rich in globular formations is re-inoculated into a medium containing the same quantity of radioactive phosphorus, one obtains almost exclusively globular formations. A second transplantation under the same conditions after 24 hr. also shows many whole or destroyed globular formations, but mostly rods and short filaments. At the third transplantation the globular formations disappear almost completely and the culture consists of long filaments, rods and normal bacilli. Still more transplantation in the presence of phosphorus-32 produces a more and more normal culture, containing only a few filaments or globular formations.

When *Proteus P*18 develops in a medium containing 16 μc. of phosphorus-32 per 100 ml. of medium, similar changes are observed but they occur slightly faster (Fig. 1*i*).

At a dose of 28 or 40 μc., beside the normal bacilli, one finds a few short filaments and globular formations after 6–9 hr., but neither long filaments nor large globular formations are observable. Apparently the morphological changes are very short-lived and incomplete and the culture quickly reverts to normal. Of course, the larger doses slow down the microbial growth very noticeably ; this ceases after about 12 hr.

The transformations which we have described suggest in many respects the *L* forms produced in the presence of penicillin[1,2] by X-rays[3].

The interesting aspect of our experiments is the shortening of the period of unusual morphology when high doses of phosphorus-32 are used, and the reversion to normal forms in spite of the continuous action of radiation. An adaptation to the beta-radiation of phosphorus-32 therefore seems likely.

The metabolism of the bacterial forms produced by phosphorus-32 and its action on other bacilli are under investigation.

This work was done with the help of funds from the Institut National d'Hygiène and from the Clinique Sainte-Anne.

Autonomic Functions of the Hippocampus

AT present no definite function can be attributed to the hippocampus. In the cat and the dog, electrical stimulation of the fimbria, the main efferent tract from the hippocampus, has been reported to give rise to no detectable autonomic changes[1], although it is well known that stimulation of other components of the limbic system can elicit autonomic changes.

In rabbits anæsthetized with urethane, pentobarbital sodium or ether, it can be shown that stimulation within the ventral part of the fimbria raises the blood pressure and increases the rate and amplitude of the respiration as illustrated in Fig. 1. Stimulation within the more dorsal part of the fimbria depresses the blood pressure, but has similar effects on the respiration as shown in Fig. 2. The effects obtained from these two regions of the fimbria are qualitatively reproducible in many animals, but vary quantitatively from animal to animal.

Degenerating fibres are being traced by a modified Nauta–Gygax method[2] from lesions made in the fimbria in positions which gave a definite pressor or depressor response when stimulated. In one rat studied by Nauta[3], destruction of the caudal half of the hippocampus led to degeneration of fibres coursing through the middle and ventral parts of the fimbria, some of which continued as the medial cortico-hypothalamic tract to the periventricular zone of the anterior hypothalamus, a region which raises the blood pressure when stimulated. The fimbria is also known to contain fibres terminating in the septum and in the medial mammillary nucleus, both of which give depressor responses when stimulated (Cragg and Hamlyn, unpublished work). It is

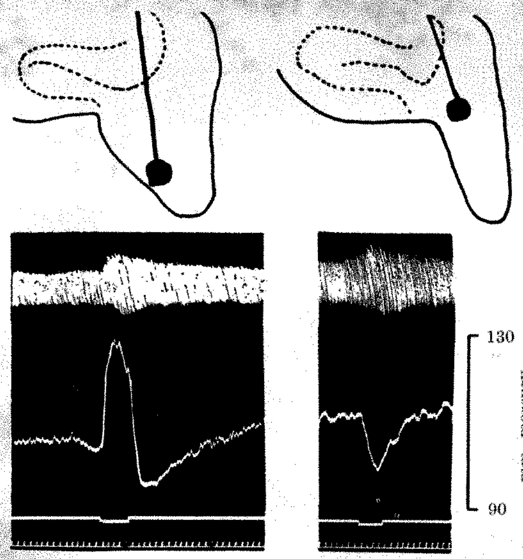

Fig. 1 Fig. 2

Figs. 1 and 2. The changes of respiration and blood pressure produced by stimulation of the fimbria at the positions indicated. Rabbits anæsthetized with urethane and ether. Time marker: 5 sec.

therefore possible that one of the functions of the hippocampus is concerned with the regulation of some of the activities of the autonomic nervous system.

Semipermeability of the Nuclear Membrane

Previous studies on the osmotic properties of isolated nuclei indicated that ions or molecules of low molecular weight readily penetrate the nuclear membrane. Of the components tested, only protein and certain other substances of high molecular weight were found to exert an osmotic effect[1,2]. The process of isolation may have marked effects on the properties of the nucleus and its membrane. In the present studies, osmotic properties of the nucleus were studied by micro-injection of certain solutions into the cytoplasm. Relatively small, unpigmented oocytes of *Rana pipiens* were used. Photographic records were obtained and all measurements were made from these. No harmful effects were observed within the cells following injection.

In some of the experiments a high molecular weight synthetic polymer, polyvinylpyrrolidone, was used (kindly supplied by Antara Chemicals, General Aniline and Film Corporation, Philadelphia). This substance, which has been used as a blood substitute, has the advantage of being non-toxic, relatively non-reactive, and of known molecular weight. The polymer was dissolved in a solution of potassium and sodium chlorides. For experiments in which potassium and sodium chlorides alone were used, the solution consisted of nine parts 0·126 *M* potassium chloride and one part 0·123 *M* sodium chloride. For the other solutions the concentrations of potassium and sodium chlorides were adjusted slightly so that all solutions had exactly the same tonicity with respect to the cell membrane (isosmotic with amphibian Ringer). The *p*H, in each case, was adjusted to approximately 6·5.

For each solution a series of about ten experiments was performed. The results indicate clearly that polyvinylpyrrolidone has an effect on nuclear volume. The injection of 0·5 per cent of the polymer causes a significant increase in volume of the nucleus, whereas 2·0 per cent or 4 per cent causes a significant decrease. 1 per cent and 1·5 per cent polyvinylpyrrolidone have very little effect on nuclear volume. If we assume that the observed volume changes are osmotic in nature, then nuclear volume is apparently dependent on the colloid osmotic pressure of the cytoplasm. Furthermore, we can conclude that the isotonic concentration of polyvinylpyrrolidone lies in the range 1–1·5 per cent. The molecular weight of this preparation of polyvinylpyrrolidone (type *NP*–K30) is reported by the manufacturer to be 40,000, and the molar concentration for the isotonic solution is therefore equal to $2 \cdot 5 - 3 \cdot 75 \times 10^{-4}$ *M*. In further experiments crystalline bovine serum albumin (molecular weight, 65,360)[3] was used. A 1·96 per cent (3×10^{-4} *M*) solution of albumin was found to cause no significant change in volume of the nucleus. An albumin solution of twice that concentration, however, caused a significant decrease in volume. Injection of a solution of potassium chloride and sodium chloride alone, which is isotonic with respect to the cell membrane (isosmotic with amphibian Ringer), as well as a solution 20 per cent more concentrated, invariably caused an increase in nuclear volume. It might be re-emphasized that the potassium chloride–sodium chloride solutions of polyvinylpyrrolidone and albumin which are hypertonic for the nucleus are isotonic with respect to the cell membrane.

These results would indicate that the nuclear membrane of the intact oocyte does not allow the free penetration of molecules of 40,000 molecular weight and larger. It is possible that some penetration does occur, but to such a small extent that it is not detectable under the experimental conditions employed. There has been no systematic attempt to determine a threshold range of molecular weight, below which the molecules would be osmotically ineffectual. Previous work with this species indicated that sucrose, with a molecular weight of 342, readily penetrates the isolated germinal vesicle nucleus, whereas egg albumin, with a molecular weight of approximately 34,500, does not[2]. On the other hand, it has been shown that blood proteins rapidly get into the nuclei of mammalian somatic cells, where they may even accumulate[4]. It would be important to show if differences exist between the nuclei of germ cells and somatic cells (or even between the same cell types of two different species) that might account for this apparent discrepancy. (See Anderson[5] for a discussion of this.) It is conceivable that active processes are involved in the passage of certain high molecular weight substances (proteins) between nucleus and cytoplasm. The presence of such an active mechanism might allow the penetration of certain large molecules through the nuclear membrane without necessarily destroying the properties of the nucleus as an osmometer. This possibility might reconcile the observations on osmotic properties of nuclei, and the apparent permeability of certain somatic cell nuclei to proteins, as has been suggested by Stern and Mirsky[6].

The work reported here was aided in part by funds from a Rockefeller grant to the Zoological Laboratory. We should like to express our sincere thanks to Prof. L. V. Heilbrunn for his advice and encouragement, and to Dr. Merkel H. Jacobs and Dr. Paul G. LeFevre for reading the manuscript.

Kinetics of Muscular Contraction in Heavy Water

VARIOUS lines of evidence, for example, involvement of sulphydryl groups and adenosine triphosphatase, suggest that the rate-limiting process for muscular contraction may be proton transfer. In this event, one would expect the rate of either isometric or isotonic contraction to be slowed up in the presence of heavy water (D_2O). According to a recent analysis[1], which of the two most affected will depend on whether activation or production of tension is involved.

Fig. 1 shows the development of isometric tension in normal and heavy water – Ringer solution after 20 min. equilibration. The reduction in rate of just over three times is completely reversible. Maximum tension and relaxation phase were not altered; action potentials in another muscle (frog sartorius) were found to be normal. These results, with the exception of 30 per cent less tension, are reproduced by normal Ringer solution with osmotic pressure increased by addition of sucrose to 1·6 times (that is, 0·416 osmolar)

Fig. 2 shows force–velocity curves for the three cases. The isotonic rate is reduced some twelve times in heavy water – Ringer solution, while for sucrose Ringer the factor is again only three.

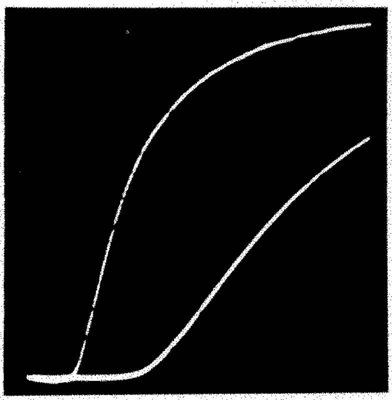

Fig. 1. Development of isometric tension in turtle (*Chrysemys picta*) retractor penis muscle at 0° C. Left to right, in normal and heavy water – Ringer solution

From this we should conclude that the reaction affected is tension production, and from the magnitude of the effect more than one (possibly three) protons are involved.

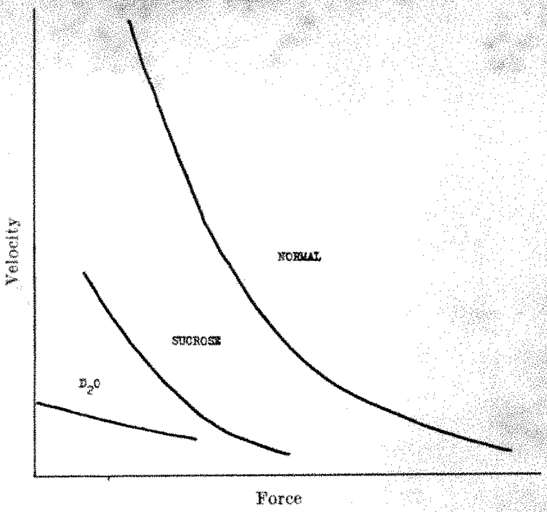

Fig. 2. Force–velocity curves of the same muscle, obtained with a continuously recording device

I am indebted to Dr. N. Geschwind for observation of action potentials by micro-electrode technique, and to the Muscular Dystrophy Associations of America for support.

Influence of Water Deprivation on Taste Sensitivity in Man

IN a previous communication[1], I presented results showing that forced loss of salt from the body is accompanied by increases in taste sensitivity to 'salt' in human subjects. Sensitivity to 'sweet', 'sour' and 'bitter' remained unchanged. In a study of the preference behaviour of thirsty (deprived of water for 17½–19 hr.) and non-thirsty rats, Young and Falk[2] report that thirsty rats reject hypertonic solutions and tend to prefer water to hypotonic salt solutions. Thus it appears that the preference behaviour of rats deprived of water is practically the opposite of that shown by rats deficient in salt. In view of the finding that salt deficiency is accompanied by an increase in sensitivity to salt, Young and Falk's results suggest that water deprivation may be accompanied by a decrease in sensitivity to salt.

To check this, four human subjects (*H*, *R*, *J* and *C*) were rendered water-deficient and their sensitivity to 'salt' (sodium chloride) and 'sour' (sulphuric acid) was studied. Details of the procedure used to establish absolute thresholds were reported previously[1]. After rinsing the mouth, subjects were careful to spit out as much as possible of the fluid before swallowing. Nevertheless, very small amounts of fluid were undoubtedly swallowed during testing.

Throughout the control, experimental and recovery periods of the experiment (nine days for subjects *H* and *R* and eight days for subjects *J* and *C*) the overall caloric value of the food intake of all subjects was controlled. It averaged about 2,100 cal./day for *H*, about 2,650 cal./day for *R*, about 2,840 cal./day for *J* and about 2,450 cal./day for *C* (all food was weighed; nutritional values and water content were calculated from ref. 3). The proportion of protein was kept fairly constant throughout the experiment, but the proportion of carbohydrate was slightly reduced and that of fat slightly increased during the experimental period in order to keep the 'dry' diet reasonably palatable. Intake of salt was also slightly less during the experimental period. During the control period of three days for all subjects and the recovery period of three days for subjects *H* and *R* and two days for subjects *J* and *C* water was allowed *ad libitum*.

For subjects *H* and *R* the experimental period lasted from 8.30 a.m. on the fourth test day until 11.30 a.m. on the sixth test day; for subjects *J* and *C* from 9 p.m. and 6 p.m. on the third test day until 10.30 p.m. and 12 p.m. on the sixth test day, respectively. During the experimental period no fluid was taken deliberately and all food eaten was of a very low water content. Total water intake from food and oxidation over this period was 659 ml. for subject *H*, 834 ml. for *R*, 1,000 ml. for *J* and 837 ml. for *C*. Subjects *H* and *R* carried out a 2-hr. sweating session (in a hot room at 95° F. wet bulb, 105° F. dry bulb) during the morning of the first day of water deprivation. Losses in body-weight, recorded over the experimental period, were 2·500 kgm., 3·150 kgm., 2·250 kgm. and 2·900 kgm. for subjects *H*, *R*, *J*, and *C* respectively. Increases in the concentrations of sodium in the serum and chloride in the plasma and in hæmatocrit percentages also occurred in all subjects (see Table 1).

The means of thresholds for 'salt' of subjects *H* and *R*, determined daily at 9.00 a.m. and 4.45 p.m., and of subjects *J* and *C*, determined daily at 9.00 a.m. and 11.30 a.m., are presented in Fig. 1. The means of thresholds for 'sour' of subjects *H* and *R*, determined daily at 2.15 p.m., and of subjects *J* and *C*, determined daily at 2.30 p.m., are also shown in Fig. 1.

Table 1. CONCENTRATIONS OF SODIUM IN SERUM, CHLORIDE IN PLASMA AND HÆMATOCRIT PERCENTAGES FOR SUBJECTS *H*, *R*, *J* AND *C**

Day of experiment	Serum-sodium (m.equiv./l.)		Plasma chloride (m.equiv./l.)		Hæmatocrit (per cent)	
	R	*H*	*R*	*H*	*R*	*H*
3	147	147	109	112		
6	160	155	118	115	48·7	44·9
7	148	146	107	111	48·4	44·8
9	148	144	108	110	46·5	40·9
	J	*C*	*J*	*C*	*J*	*C*
3	144	137	109	104	50·1	45·1
6	147	141	111	113	51·9	46·7
8	144	141	110	108	49·2	46·1

* Thanks are due to Prof. R. A. McCance, Department of Experimental Medicine, University of Cambridge, for arranging the taking and analysis of these samples.

From these results, it can be seen that loss of body-water was accompanied by a decrease in sensitivity to 'salt', whereas sensitivity to 'sour' remained unchanged.

The results also show that sensitivity to 'salt' was less acute at 9 a.m. than at the later session on the same day. I have found evidence of similar systematic fluctuations in sensitivity to 'salt', 'sweet', 'sour' and 'bitter' solutions during the course of a day of normal food intake (to be reported elsewhere). The variations are statistically significant. The degree of variation appears to depend largely on the caloric value and composition of the food intake. Systematic variation during the day in taste sensitivity has also been reported by others, namely, Hammer ('sour'), Goetzl *et al.* ('sweet') and Irvin and Goetzl ('salt')[4]. In the present results, the degree of variation from 9 a.m. to times later in the day has not remained constant during the period of decreased sensitivity to salt. This is probably due to the fact that the tendency for sensitivity to increase from the 9 a.m. session to the later session was partly counteracted by the tendency for it to decrease due to the increasing loss of body-water over this period. It appears, then, that the factors responsible for the changes in taste

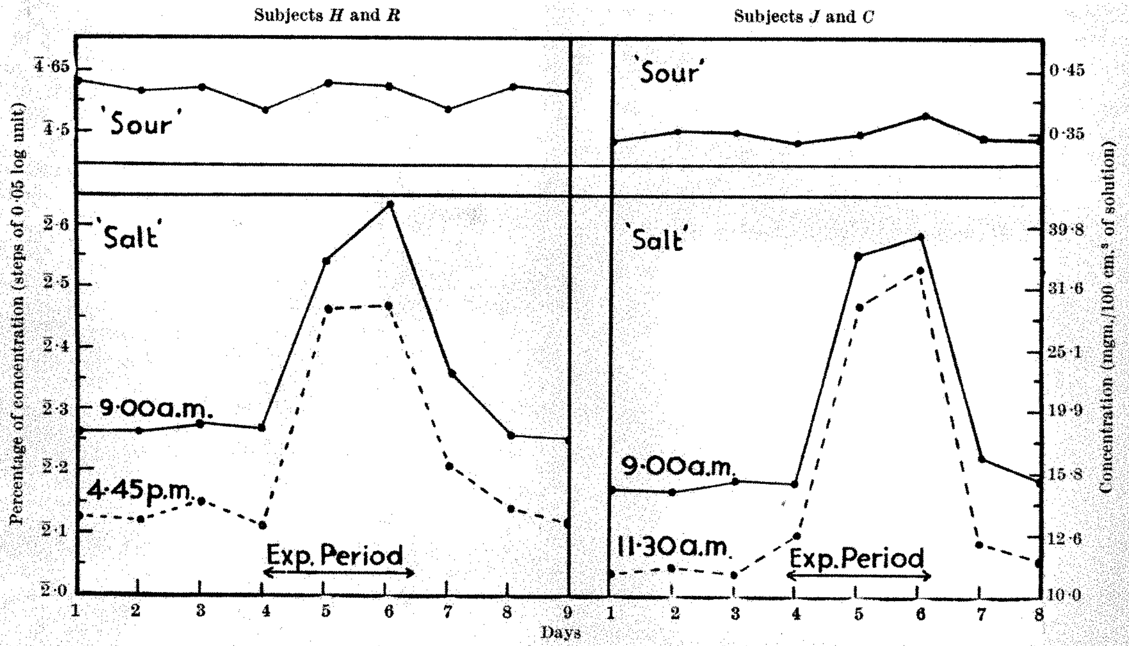

Fig. 1. Mean absolute thresholds for 'salt' and 'sour' for subjects *H* and *R* (left) and for subjects *J* and *C* (right). Each threshold is the mean of eight determinations, four from each of two subjects

sensitivity which occur during the day are independent of the factors causing the observed changes in sensitivity which were specific to 'salt'.

Since losses in body-salt, which result in a fall in the concentration of sodium in the extracellular fluid, were accompanied by increases in sensitivity to salt, and losses in body-water, which result in a rise in the concentration of sodium in the extracellular fluid, were accompanied by a decrease in sensitivity to salt, it appears likely that these changes in sensitivity are related to the concentration of sodium, and possibly the osmotic pressure, of the extracellular fluid (the osmotic pressure is usually, but not always, dependent on the concentration of sodium in the extracellular fluid). Changes in the volume *per se* of the extracellular fluid would not appear to be related to the sensitivity changes, since under both conditions reductions occurred in the volume of the extracellular fluid.

This investigation is made possible by the grant of a Hackett studentship from the University of Western Australia, for which special thanks are due.

Nitrite Accumulation in the North-East Tropical Pacific

During two oceanographic expeditions in waters off the Mexican and Central American coast, nitrite analyses were made on water samples from between the surface and 800 m. depth in order to obtain information on the decay process of planktonic material.

Because of the intermediate position of nitrite in the nitrogen cycle between ammonia and nitrate, its concentration is determined by the ratio of ammonia oxidation to nitrite oxidation, in case of nitrification. The bacteria responsible for the oxidation of ammonia do not occur freely suspended in the open ocean but are attached to plankton organisms. Dying plankton often accumulates in the thermocline, and in culture experiments large quantities of nitrite appear soon after the cultures die[1]. Many investigators have found a nitrite peak associated with the thermocline layer. In highly productive, tropical areas[2] conditions are especially favourable for a strong decay of planktonic material. As a result of this decay all 20 stations occupied 50–650 miles off the American coast from the Gulf of Panamá (4° N.) to the southern tip of Baja, California (23° N.), show this nitrite accumulation in the thermocline layer (Fig. 1).

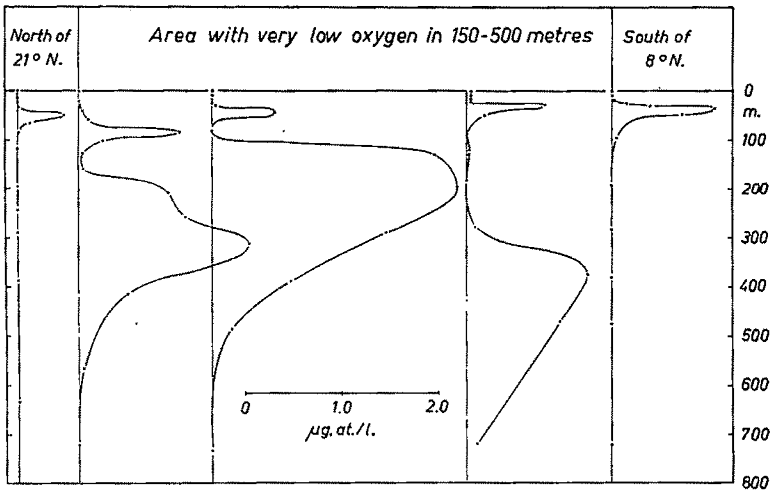

Fig. 1

Denitrifying bacteria also exist in the sea, some of which are able to reduce nitrate to nitrite under anaerobic or nearly anaerobic conditions in the presence of abundant organic matter. In most areas of tropical oceans there is, even in the oxygen minimum layer, some oxygen present. Wattenberg[3] reported 0·37 cm.^{3}/l. as the lowest oxygen value measured on the *Meteor* Expedition in the South Atlantic. Due to the weaker subsurface circulation in the Pacific and a relatively high production in its eastern part, a large body of water is found within which the oxygen content is almost zero[4]. This water of low oxygen content extends off the American coasts between 8° N. and 21° N. in an intermediate layer between 150 and 1,000 metres. Fig. 1 reveals that only the area with very low oxygen content is also a region with a second, deep nitrite maximum, with values up to 2·5 µgm. at./l. Both features, low oxygen and high nitrite concentrations, are found between 150 and 500 metres.

From an oxygen versus nitrite plot the two nitrite maxima are clearly distinguishable. Nitrite from the upper maximum is found within a wide oxygen range from about 1 to 5 cm.^{3}/l., due to the very sharp thermocline with which this maximum is associated. The nitrite values of the deep maximum occur only in water with less than 0·10 cm.^{3}/l. oxygen, which suggests that the deep nitrite maximum is produced by reduction of nitrate to nitrite. Similar observations of a deep nitrite maximum were made by Gilson[1] in the eastern Arabian Sea, but at that time could not be explained.

This work was partly supported by funds of the Inter-American Tropical Tuna Commission, Scripps Institution of Oceanography, La Jolla, California. A detailed report of this study will be published elsewhere.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH CHEMIST, Senior Research Officer or Principal Research Officer grade (with a first- or second-class honours degree and substantial research experience, preferably in the field of inorganic or physical chemistry; radiochemical experience an advantage), to take charge of a group in the Chemistry Section, Australian Atomic Energy Commission Research Establishment, Lucas Heights, Sydney, for a programme including the study of two high temperature reactor systems and the reprocessing of a range of nuclear fuels—Australian Atomic Energy Commission Liaison Officer, Australia House, Strand, London, W.C.2 (September 19).

RESEARCH ASSISTANT (with a good degree in mining, engineering or pure science) TO THE PROFESSOR OF MINING—The Registrar, The University, Sheffield (September 20).

ASSISTANT LECTURER IN BOTANY—The Registrar, The University, Manchester 13 (September 30).

ASSISTANT LECTURER or LECTURER (with industrial experience and preferably with a knowledge of the aspects of control engineering which are related to production engineering) IN THE DEPARTMENT OF MECHANICAL ENGINEERING, to work in the general field of mechanical engineering but to take particular interest in control engineering—The Registrar, The University, Leeds 2 (September 30).

SENIOR LECTURER or LECTURER (with special qualifications in plant physiology and preferably with interests and research experience in biochemistry) IN BOTANY—The Registrar, The University, Manchester 13 (September 30).

SENIOR LECTURER or LECTURER IN GEOLOGY at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 4).

ASSISTANT DIRECTOR OF RESEARCH IN GENERAL SURFACE CHEMISTRY AND COLLOID SCIENCE—Dr. F. B. Kipping, University Chemical Laboratory, Lensfield Road, Cambridge (October 10).

LECTURER (with interests in physical and/or inorganic chemistry) IN CHEMISTRY at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 10).

SENIOR LECTURER (with special interest in analysis) IN MATHEMATICS (PURE MATHEMATICS) at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Sydney, October 11).

AGRICULTURAL SUPERINTENDENTS (with a degree in agriculture or horticulture and at least two years postgraduate training or experience) in British Guiana, for duties mainly concerned with agricultural extension work and management of demonstration farms and stations—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/30/011.

ASSISTANT LECTURER AND DEMONSTRATOR IN PHYSIOLOGY—The Secretary, Queen Elizabeth College, Campden Hill Road, London, W.8.

METEOROLOGIST (with a good honours degree in mathematics and/or physics, or with a good honours degree in geography with subsidiary mathematics or physics, preferably with meteorological service experience in analysis and forecasting), for the East African Meteorological Department, for duties mainly of chart analysis and weather forecasting but possibly also to undertake research—Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.57/88/01.

PLANT PATHOLOGIST (with a good honours degree in agriculture or natural science and at least one year's postgraduate training in mycology and plant pathology, preferably with a knowledge of virus diseases) with the Tanganyika Department of Agriculture, for field and laboratory work in the diagnosis and investigation of fungal and bacterial diseases of crop plants and testing of control measures—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/08.

PRINCIPAL FISHERIES RESEARCH OFFICER (with a good honours degree in zoology and considerable postgraduate experience in fisheries research) with the Federation of Nigeria, to lead a small group of scientists and technicians in either sea fisheries research or inland fisheries and fish culture research—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/14/03.

REGISTRAR (with wide experience in educational administration)—The Principal, Royal Technical College, Salford.

RESEARCH ASSISTANTS (honours graduates in physics), for problems concerned with fast particle techniques, gas discharges, spectroscopy and electronics—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

RESEARCH DEMONSTRATORS (2) IN PHYSICS—The Registrar, The University, Leicester.

DIFCO ***microbiological reagents and media***

Bacto-Dehydrated Media for Microbiological Assay of
VITAMINS and AMINO ACIDS

These *media* contain all the necessary nutriments for the growth of specified test organisms for the microbiological assay of vitamins and amino acids except for the component under assay. These basal media require only the addition of specified increasing amounts of the vitamin or amino acid being assayed to obtain a growth response which may be measured by acidimetric or turbidimetric methods for the construction of standard curves. The vitamin or amino acid content of the material under assay is determined by adding appropriate concentrations of the test substance to the basal medium and comparing the growth response obtained with that of the standard.

BACTO-RIBOFLAVIN ASSAY MEDIUM
BACTO-NIACIN ASSAY MEDIUM
BACTO-THIAMIN ASSAY MEDIUM
BACTO-PANTOTHENATE ASSAY MEDIUM
BACTO-B_{12} ASSAY MEDIUM USP
BACTO-CS VITAMIN B_{12} AGAR
BACTO-FOLIC ACID ASSAY MEDIUM
BACTO-PYRIDOXINE ASSAY MEDIUM
BACTO-BIOTIN ASSAY MEDIUM
BACTO-CHOLINE ASSAY MEDIUM
BACTO-CF ASSAY MEDIUM
BACTO-TRYPTOPHANE ASSAY MEDIUM
BACTO-LEUCINE ASSAY MEDIUM
BACTO-METHIONINE ASSAY MEDIUM
BACTO-LYSINE ASSAY MEDIUM
BACTO-ISOLEUCINE ASSAY MEDIUM
BACTO-ARGININE ASSAY MEDIUM
BACTO-TYROSINE ASSAY MEDIUM
BACTO-CYSTINE ASSAY MEDIUM

The *method* employed in carrying stock cultures of the test organisms and preparing the inoculum for microbiological assay is important. The following media have been developed especially for carrying stock cultures and for preparation of the inoculum:

BACTO-MICRO ASSAY CULTURE AGAR
BACTO-MICRO INOCULUM BROTH
BACTO-B_{12} CULTURE AGAR USP
BACTO-B_{12} INOCULUM BROTH USP
BACTO-NEUROSPORA CULTURE AGAR

BACTO-VITAMIN FREE CASAMINO ACIDS, dehydrated, is an acid hydrolysate of vitamin-free casein prepared especially for laboratories investigating microbiological assay of vitamins.

Over 60 years' experience assures UNIFORMITY · STABILITY · ECONOMY

MUSEUMS AND ART GALLERIES AS CULTURAL CENTRES

FOR many years the Museums Association has in one way and another been pressing for some form of Government assistance to help, and even in some cases to preserve from extinction, the many small society and trustee museums in Britain. From time to time various organizations have stressed the importance and urgency of the claims of museums and art galleries and recently the Bow Group prepared a detailed memorandum on the subject*.

The main part of this report naturally surveys the facts regarding the present position of the museum and art gallery service. It is pointed out that this is complex and that the official relationships between the national and provincial institutions are thoroughly unsatisfactory. With the increasing leisure of many people and the great advances in organized education made in recent years, it is indeed imperative that museums and art galleries should be in a far better position than they are to deal with not only the preservation of their buildings and contents but also the wider problems of visual education.

The memorandum clearly indicates the complexity of organization in the museum and art gallery field, and points out that some are financed direct from the Treasury, others from the Ministry of Education, some from county or municipal rates and yet others from universities and various societies and trustees.

The fundamental aims of museums and art galleries are discussed, and in addition it is rightly stated that each institution should be a cultural centre to its community, where people may meet their friends in the context of scientific and beautiful objects and where amateur activities can be pursued under favourable conditions.

The report cites outstanding examples of what is urgently required, including the rebuilding of the damaged British Museum galleries, the raising of the purchase grant of the National, Tate and other art galleries, the provision of museums and art galleries in areas where the inhabitants have no ready access to such institutions, and the adequate financing of several now threatened with closure.

The survey naturally leads to recommendations, and emphasizes the need for the Government to realize that such a problem exists and that its very complexity demands a solution at the national, rather than the local, level. In order to achieve a flourishing and effective museums service it is recommended that a Royal Commission should be appointed at once and that some form of central advisory body should be established to integrate the work of the national and provincial museums. This could be done either by extending the powers and membership of the Standing Commission, or by the Ministry of Education, or by setting up an organization comparable to the University Grants Committee. Such a body should have at its disposal a block grant for distribution to individual museums, and in this connexion it is suggested that the grants should be made on the recommendation of regional museum bodies.

The memorandum issued over the signatures of Mr. Richard Carless and Miss Susan le Roux includes an appendix on the importance of the collections and work of the National Gallery, expressing the hope that it will be possible, as indeed it is eminently desirable, to secure the Hampton site for this great national institution.

The main theme of the recommendations of this important memorandum is in complete accord with that of other organizations vitally interested in the future of the museums and art galleries of Great Britain, and it is hoped that the Government will take heed of the unanimity of these representations.

INTELLECTUAL MYSTICISM

The Manifold and the One

By Agnes Arber. Pp. xiii+146. (London: John Murray (Publishers), Ltd., 1957.) 18*s*. net.

AGNES ARBER'S book is a study of the problem of the One and the Many from the standpoints of philosophy and of mysticism, and it is also a record of a personal quest continued over a long period. This personal note, though sternly restrained, gives an interest to her writing which carries the reader on through the somewhat compressed material which she has brought together from an amazing variety of sources. She makes no secret of her involvement in the problem. "I still remember vividly the glow of emotion aroused in me by the idea—which I discovered inside myself and treasured as my very own—that all such qualities as justice, love, and truth, are in reality *one*", she writes at the beginning of her book, and the "glow" appears again in her brief summing-up at the end.

Brushing aside as irrelevant the discussions of the Logical Positivists and the Semanticists, she considers the systems of metaphysicians from Anaxagoras onwards, in the conviction that most of them are based, consciously or unconsciously, on an intuition of the ultimate unity of the manifold or "the craving to see the universe *sub specie unitatis*". There is, in her view, a close affinity between the philosophical search for Reality and the mystic's search for union with the One. It is, of course, obvious that many systems end in a mystery which is not just a blank wall, but a Reality which is apprehended but not comprehended. In the survey of the mystics, which forms the most valuable contribution of her study and embraces both eastern and western examples, she gives the greatest weight to those that are least emotional and most intellectual. The essence of the mystical experience is "direct and unmediated contemplation characterized by a peculiarly intense awareness of a Whole as the Unity of all things".

It is difficult to convey in a review the quality of this book which, by reason of the rich material on which the writer works, calls for comment on almost every page. Probably only those who have themselves experienced the nostalgia for unity will be wholehearted students, but even those who are strangers to this 'intuition' can learn much from it about an important tendency in human thought and emotion through the ages. The Christian theologian will have his reservations and questions, particularly on the place of values in the Unity of the Manifold which, in the author's view, is the ultimate Reality. The distinctions of 'good' and 'evil', we are told, on this, the highest, plane vanish. The lines of Rumi—"The man of God is beyond fidelity and faith, To the man of God right and wrong are alike"—are quoted with approval. Why, one might ask, is the mystic way largely a way of 'purification', if, in the end, the One who is the end of that way is indifferent to all human values ? Perhaps we may see here why the Christian Church has been somewhat cautious about mysticism, and if this book has a defect, it is that it is too heavily weighted on the intellectual side. At any rate many, who have loved God and experienced union with Him, have loved Him because they believed Him to be the supreme Good and the enemy of evil. For such persons the beginning of their pilgrimage is to range themselves on His side. They have their right to be heard.

This is a valuable work and a learned one. It deserves to be read and pondered.

W. R. MATTHEWS

DUST, SMOKE AND MIST

Particulate Clouds

Dusts, Smokes and Mists—Their Physics and Physical Chemistry and Industrial and Environmental Aspects. By H. L. Green and W. R. Lane. (Spon's General and Industrial Chemistry Series.) Pp. xix+425+8 plates. (London : E. and F. N. Spon, Ltd., 1957.) 70*s.* net.

IMPLEMENTATION of the Clean Air Act requires control of the emission of dust and smoke from furnaces. This is partly achieved by the mode of operation of the process and partly by the collection of particulate material from the flue gases. The methods of collection that are available include gravitational settling, inertial separation, scrubbing, electrostatic precipitation, sonic and ultrasonic agglomeration. The variety of these methods illustrates the many mechanisms that operate in a particulate cloud. Physicists and chemists have contributed much to understanding of clouds during the past decade, following on the pioneer work of Gibbs, Patterson, Whytlaw-Gray, Drinker, Hatch and others. Notable contributions have been made by the Chemical Defence Experimental Establishment at Porton Down, and it is not unexpected to find that, in a book from this school, the authors have rightly attempted a unified treatment of the whole subject.

The task was by no means simple for, as the four pages of literature abbreviations show, relevant work has been published in a heterogeneous set of journals. Those venturing into this field of colloid science for the first time might well be glad of the further warning that the quality of the literature is uneven. The selected references given at the end of each chapter are, therefore, particularly valuable.

In the discussion of the physics and physical chemistry of clouds in the eight chapters of Part I, the essential instability of a cloud, owing to the mechanisms whereby the constituent particles can either grow or shrink, is clearly presented. Following chapters on the production of clouds and their physical characteristics, there is an interesting account of their optical properties. The basic electromagnetic theory has long been known, and, now that the necessary computations have been carried out, experimental data can be interpreted adequately. There follows a long account of coagulation, one of the most important properties of a cloud ; this chapter is fundamental to a proper understanding. The next two chapters on deposition and filtration and on sampling and estimation give descriptions of the many ingenious devices that have been developed, dependent on such varied mechanisms as impaction on an obstacle in a flowing stream, thermal and electrostatic precipitation. Lastly, there is an up-to-date discussion of diffusion in the atmosphere.

Industrial and environmental aspects are covered in Part II. Following a brief chapter on collection, accounts are given of health hazards, atmospheric pollution, aerosols in Nature and, lastly, some uses of particulate clouds. These titles indicate the range of phenomena in which clouds have importance, and the treatment illustrates the authors' thesis that many different types of cloud have essentially the same properties. Thus, the theory of impaction of particles on obstacles is applied in the icing of aircraft, the filtration of dusts and smokes, the capture of windborne pollen, the growth of raindrops and the application of insecticidal aerosols.

These examples serve as an illustration of the value of classical scientific studies at the present time, not only to elucidate natural phenomena but also to improve the operation of industrial equipment. Newer as well as the older technologies have need of the knowledge of clouds gained in the past thirty years. Scientists and technologists will find in this timely book a worthy introduction.

The book is well printed and is substantial enough to warrant its price.

R. L. BROWN

PRODUCTIVITY AND SOCIAL ORGANIZATION

Productivity and Social Organization

The Ahmedabad Experiment—Technical Innovation, Work Organization and Management. By A. K. Rice. Pp. xiii+298. (London : Tavistock Publications, Ltd., 1958.) 35*s.* net.

IMPROVED technology has greatly contributed to the rising level of industrial productivity. But there is a danger in some situations that technological change may neglect the social and psychological needs of the human operator and so reduce substantially the potential rise in output per man-hour. There are a number of studies of the human implications of technological change. But only recently has a method of analysis been evolved which treats a production system as an organic whole, and enables the social dimension to be designed to meet both human and technological requirements in a systematic manner. This method of analysis has arisen from the concept of a 'socio-technical' system introduced by E. L. Trist and his colleagues, of whom Mr. Rice is one, at the Tavistock Institute of Human Relations. The concept of a socio-technical system, together with the developing theory of social structure and the work of W. R. Bion on the conscious and unconscious behaviour of small groups, lays much of the conceptual foundation for the experiments carried out by Mr. Rice in the operational setting of a large Indian textile firm and described in this book.

Mr. Rice worked as a management consultant, and his primary professional responsibility was toward his client. The fact that his client's share prices doubled in value after his three-year period of work at a time when other textile firms were failing suggests that Mr. Rice's contribution in this role was by no means ineffective. But he also worked in an operational research role. Here he used as his quantitative data the commercial and technical facts of the firm, and as his qualitative data the feelings of people. His findings are logically presented and he offers some challenging hypotheses concerning both technological change and the theory of organization.

Mr. Rice's first task was to examine the working of the automatic loom sheds, where despite the introduction of Western technology, productivity and quality were low. An analysis of the socio-technical system showed that "because the workers formed only an aggregate and not a working group, and because the jobs were broken down into component operations" stable relationships were impossible. Nobody experienced either as an individual or in a group the satisfactions deriving from the "completion of a whole task". The production system was therefore re-organized to provide adequate satisfactions in the social dimension. This was followed by a similar reorganization of the non-automatic loom sheds. Despite many difficulties, some of them peculiar to the Indian scene, productivity and quality rose to the levels required by management, in both sheds.

Mr. Rice's third major task was to examine the management organization of the firm. His theory of the differentiation of organization structure into managing and operating systems represents a radical departure from the outworn 'machine' theory of organization and provides an organic model for the study of organizations. Using this model, which is derived from von Bertalanffy's theory of open systems, it is possible for the first time to determine by means of operational criteria where and at what level management functions such as control and services should be placed in an organization. As Mr. Rice remarks, "difficulties between managers are frequently caused by confusion between control functions and operations", and one can only guess at the loss of both productivity and human satisfaction in almost every firm for this reason alone. This new thinking deserves most serious consideration, and I believe it will prove to be a major contribution to the theory of social organization. If there is any criticism to be made, it is that more detail would have been welcomed on the organizational changes and the difficulties which were incurred in making them. No doubt we shall have to wait for this until another occasion. The fact that these remarkable experiments took place in an Eastern culture demonstrates not the limitations but the wide applicability of this integrated approach to a central problem of our time. This is an important book not only for social scientists but for all who are concerned with the tasks of administration in any field.

S. DAVID M. KING

JOLLY GOOD COMPANY

Earth's Company

By Leslie Reid. Pp. xi+221+12 plates. (London: John Murray (Publishers), Ltd., 1958.) 25*s*. net.

WITHIN the last decade a spate of books describing various aspects of biology has been published with the avowed aim of interesting the intelligent layman and setting before him different facets of the great natural panorama. Some of these books, notably in the New Naturalist series, have been very successful, combining interest, accuracy, and a dispassionate approach to scientific problems which are wholly admirable. "Earth's Company" makes an attempt to follow this pattern, but goes off on a rather different tack.

Leslie Reid has put three component parts into his book. It is on the surface a description of many aspects of, mainly animal, ecology such as coloration, prey–predator relationships, parasitism, movement of individuals and societies, courtship, etc., and an attempt is made to show that "each single phenomenon of nature has no meaning, no existence, except by virtue of its relationship with all the other phenomena" (p. 208). The ecological accounts are interesting, but on the whole elementary and rather sketchy. In fact in many places the author apologizes for the summary nature of his treatment; for example, work on behaviour in mammals is discussed in a very vague paragraph of ten lines.

However, if one assumes, as one must, that this book is intended for a lay audience, then these weaknesses may be excused. There are, however, a number of inaccuracies; for example, on p. 34 it is stated that "the dominant plants . . . are always the most numerous" and that "natural mutations are extremely rare" (p. 124). These statements depend on the definition of the dominant plant, for if an oak tree is the dominant in an oak wood then there are certainly many more herbaceous plants than there are oaks, and mutations are only rare if one is thinking in terms of one particular mutation at a certain locus in one individual, but in large populations with many loci each capable of more than one mutation then the problem of rarity is not so insuperable.

At a slightly sub-surface level, the author is directing attention to the beauty and intricacy of many natural processes. It is this aspect of the book which is most satisfactory, and it leaves the reader with a sense of marvel and maybe even of awe. The examples are chosen to fulfil this special purpose and they do so very well. His statement, however, that to scientists "the æsthetic appeal of their subject seems to be one that many of them feel ashamed of" is, I feel, unjust and very often untrue, for most scientists are conscious of the beauty that can and does lie in their material, in their apparatus, and in their experimental and mathematical proofs.

The third component of this book follows naturally from what I have called the sub-surface level, for he states that since the world of Nature is strange, beautiful, intricate, yet finely adjusted to operate as a unit, then there is "in it striking evidence of some directing intelligence" (p. 143). From this philosophic standpoint much of the material comes to be presented in a very teleological manner; for example, "marine animals . . . will avoid water that is fresh, because if they fail to do so they will perish" (p. 45). Such an attitude despises "the laws (if they can be called laws) of chance" (p. 124), and in consequence minimizes the achievements of modern genetics and replaces these by a mystic power. Thus evolution becomes a process in which "it is as though (and why not ?) the change had been foreseen and allowed for in the course of the animal's evolution" (p. 140).

This is not a bad book. It is well written and illustrated, full of interesting examples and personal anecdotes, but the theme is too grand for 221 pages and its insistence on direction by a "guiding intelligence" may ring very strangely in the ears of those of its readers with a biological training.

Alan R. Gemmell

TREES AND SHRUBS

The Book of Flowering Trees and Shrubs

By Stanley B. Whitehead. Pp. 244+63 plates in colour. (London and New York: Frederick Warne and Co., Ltd., 1956.) 15*s*. net.

THIS pocket-size book is a companion volume to "The Book of Garden Plants" by G. A. R. Phillips, and is illustrated by the same artist, Miss Joan Lupton. It deals with shrubs, small trees and climbers, and by far the greater part of the text, 178 out of a total of 244 pages, is devoted to brief descriptions of 230 genera (not 240 as stated in the preface). Seven genera are divided into two or more parts, and each part is dealt with as though it was a genus, so that altogether there are 248 accounts of genera and subdivisions of genera, each with notes on the species or a selection of the species. The genera are arranged alphabetically, and each genus or subdivision is illustrated by a small coloured figure of one of its species. These figures, set four on a page, are sufficient to give the reader some idea of the sort of plant described, but they suffer the usual defect of their kind, namely, the almost complete failure to render the green of the leaves even approximately the right colour. The information given in the text is reasonably accurate, and the book may justly be regarded as "a simple and non-technical guide" to the choice, identification and qualities of flowering shrubs and small trees for the modern garden—which is what it is intended to be. As such, it should prove very useful. It must be pointed out, however, that many of the genera included are hardy only in the mildest parts of the British Isles.

In addition to the descriptive matter, there are chapters on shrubs in the modern garden, soils and situations, planting and propagating, and care of trees and shrubs. Short lists of species suitable for different soils and various situations are given, there are an illustrated glossary and, finally, an index. A reference to the method of propagation is given for each genus, and there are ten pages of details about the various methods; these details scarcely seem necessary in a book of this kind.

There are occasional examples of slipshod writing like "The genus is one of three species . . .", and the author has an irritating habit of using the word 'group' instead of 'genus'. The word 'trees' in the account of *Nuttallia* was no doubt a slip of the pen, and the same may account for the home of *Acer griseum* being given as Cochin China instead of Central China. *Stranvaesia davidiana* is a native of China, not of the Himalayas. *Rhododendron griersonianum*, shown on Plate 50 as an example of a hybrid rhododendron, is a good species, while *R. bullatum*, shown as a deciduous species, is an evergreen. One understands, and sympathizes about, the unfortunate oversight which led to the printing on p. 191 of "dry, splitting-capsule seed-vessel"—it happens to us all—but I have quite failed to elucidate "*M[alus] trilobata*, Syria, becomes a fine accent with columnar growth to thirty feet, . . .". Incidentally, this species is recorded from Palestine and the Balkan Peninsula in addition to Syria.

J. Robert Sealy

DYNAMIC BIOCHEMISTRY

Dynamic Aspects of Biochemistry

By Prof. Ernest Baldwin. Third edition. Pp. xx+526. (Cambridge: At the University Press, 1957.) 37*s*. 6*d*. net.

THIS has become a classic among biochemistry books. Prof. Baldwin received an international prize for writing it, and it has been translated into half a dozen languages including Russian and Japanese. It has long been a best-seller, valued alike by students and their teachers. It was natural, therefore, to feel anxiety on opening this new edition, lest the book might have lost its familiar and unique character. The first glance was reassuring. The author's well-known whirligig arrows, indicating coupled reactions, still cover the pages; one still learns that spiders excrete guanine; the sequence figs, fire-flies and fishes is still found in the new, shortened index. Having said this, the reviewer has to admit to a feeling of disappointment that some of the most outstanding advances of the past five years have not found their way into this new edition. Among these, the researches of Sanger on insulin and of du Vigneaud on the posterior pituitary hormones at once come to mind. Perhaps the author thought of these as structural rather than dynamic aspects, but he must have found it hard to exclude them. Again, some discussion of the biosynthesis of sterols and porphyrins and a more up-to-date account of the thyroid hormones would have been welcome.

The difficulty, of course, is to suggest what could have been left out to make room for new material, and opinions will, no doubt, differ on this. The book does not claim to be a complete text-book of biochemistry. Indeed, one of its great merits is that it is selective, and students will be thankful that its size (and its price) have not been much increased. There are, though, some sections, carried over from the original edition, which might perhaps have made way for more live topics. For example, less space might have been given to the descriptions and structures of some of the more uncommon nitrogenous bases. The obscure artefact creatone occupies half a page, though noradrenaline and 5-hydroxytryptamine are, apparently, not mentioned anywhere. The main consideration, though, is that Prof. Baldwin has chosen to write on selected topics which interested him, and has done it supremely well, in language which is simple, forthright and vivid.

It would be wrong to give the impression that this edition does not contain any new material. To mention examples, there is a new chapter on the photosynthesis of carbohydrates in green plants, the chapters on the metabolism of carbohydrates and of fats have been substantially revised, the sections on purine synthesis, on oxidation systems and on subcellular fractions have been enlarged, and many small revisions have been made throughout the book. A good many misprints have been allowed to slip through, more than would have been expected in a book of this importance.

Biochemists will be grateful to Prof. Baldwin for rejuvenating his famous book and will wish it many further years of vitality. Of course it still carries its original dedication "To Hoppy". Gowland Hopkins's teaching and outlook still permeate it: there could be no higher recommendation. D. C. HARRISON

ALL ABOUT RHEOLOGY

Rheology

Theory and Applications, Vol. 2. Edited by Frederick R. Eirich. Pp. xiii+591. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 18 dollars.

IN his preface, the Editor discusses three criticisms from reviews of the first volume: "overlap or repetitions, unequal approach or even conflicting views, and non-uniformity of nomenclature" (see *Nature*, 179, 1207; 1957). If one is prepared to accept his views on these three points, there is indeed little to criticize in the second volume. Like the first, it contains a series of admirable essays on subjects of current rheological interest, by authoritative writers.

But I cannot altogether accept the Editor's dismissal of these earlier criticisms. While some overlapping is inevitable and even desirable, the size and the price of the book might have been reduced with some advantage by excluding material readily available elsewhere. One can scarcely suppose that this three-volume work, important as it is, will serve as the only source of information for any rheologist who is sufficiently advanced in his subject to follow its treatments. The most striking example is an otherwise excellent chapter on fibres by R. Meredith. This author edited and largely wrote a whole book[1] on this subject only two years ago. There would seem to be little advantage in including a fifty-page summary of this in the present work.

On the question of symbols, one appreciates the Editor's difficulties with the more specialized properties and concepts; but at least most English-speaking rheologists are already in fairly general agreement on the symbols which are most widely used. It is welcome news that "it is hoped that, by the time the third volume is ready to go to press, efforts to unify nomenclature may have reached a point where they can be applied to this book".

The subject-matter of the book divides itself naturally into three parts. The first seven chapters deal with mainly theoretical aspects of the rheology of high-polymers, Chapters 8–10 are concerned with gelatin, asphalts and geo-rheology, and the last three chapters describe experimental techniques. The middle section, especially the chapters on gelatin by A. G. Ward and P. R. Saunders and that on geological problems by B. Gutenberg, are particularly valuable, since the contents are not readily available elsewhere. The practical rheologist, for whom the earlier chapters are directly applicable to his everyday work, will get relaxation and intellectual pleasure from reading this most lucid account of how elastic moduli, viscosities and relaxation times are computed for the great masses of material which stretch for many miles beneath our feet.

Chapters 11 and 12, especially the latter, contain little that is not already on the shelves of most readers, but Chapter 13, on goniometric methods, by A. Jobling and J. E. Roberts, will suggest new and exciting possibilities to many practical rheologists.

This book, like its predecessor, is beautifully produced and printed; and Volume 2 is singularly free from misprints, though the printers still seem to have trouble (p. 207) with the spelling of "Treloar".

Such stringent criticism of a book is justified only if it is felt that the work is one of outstanding importance and of exceptional merit. In the present case there can be no doubts on this score.

G. W. SCOTT BLAIR

WEIGHT REDUCTION IN THE HUMAN SUBJECT

This Slimming Business

By Prof. John Yudkin. Pp. 191. (London: MacGibbon and Kee, Ltd., 1958.) 15*s*. net.

THE medical advances, permitting more people of the Western World to reach old age, and the changed dietary habits of modern civilization associated with declining physical activity have focused attention on the need for weight control. Most accounts of this subject are either long scientific tomes on nutrition or uninformed accounts in the fashion or advertisement columns of newspapers and periodicals. This book claims to explain in non-technical language why some people are overweight and what they can and ought to do about it. It seems to be written mainly for women, but the information it presents could take an important place in the serious literature of the subject. It is, however, written in a chatty style more suited to the spoken than the written word and is likely to be appreciated more by those who would prefer to read a short newspaper article than the whole of this book.

The first seventy pages are concerned mainly with some general conceptions and misconceptions of obesity. An attempt to explain to the layman the significance of biological variation in relation to normal body-weight, although comprehensible to the scientific reader, seems to have been less successful with an overweight professional journalist of a national newspaper (*Daily Mail*, May 5, 1958).

There follows a brief but excellent account of nutrition that should enable the non-scientific reader to appreciate the reasons for the condemnation of much of the published nonsense on dieting. Pages 106–114 are not particularly illuminating—and with advantage could have been replaced by more compact pictorial diagrams.

The author then presents his case for controlling weight by reducing carbohydrate rather than fat calories. One cannot accept his implied argument that modern man is healthier on the carnivorous diet than his primitive forbears, but the general idea is sound that the fundamental fault of the present-day diets is that increasing wealth permits increasing dietary protein and fat without corresponding decrease in the intake of foodstuffs such as cakes, ice cream, biscuits and sweets. There is no doubt that many people can lose excess weight with a diet low in carbohydrate but unrestricted in protein and fat. The case for not restricting protein is unanswerable; that for allowing unrestricted fat is on less certain ground. According to Prof. Yudkin, restriction of carbohydrate will usually be associated with relatively little, if any, increase in fat, but many people will take extra cream with their fruit and butter with their peas and beans. He wisely avoids discussing the possible effects of dairy fats and unsaturated vegetable fats in increasing or decreasing, respectively, the incidence of coronary disease.

In presenting his slimming regime, the author has taken a leaf from the notebook of the diabetic. Lawrence's line-ration scheme enabled the great majority of diabetics of widely differing mental acumen to control carbohydrate intake while retaining freedom of selection of foodstuffs. Lawrence's unit was the black portion corresponding to 10 gm. carbohydrate, and all the intakes of diet were tabulated according to the number of such portions they contained; Yudkin has selected 5 gm. carbohydrate as his unit, wisely since he hopes to restrict his slimming subject to 4 or less of such units, whereas diabetic patients require much more. This scheme provides an acceptable method of caloric reduction deserving wide use.

One can quarrel with little of the scientific content of this book, although the physiological reality of the 'appestat' is open to some doubt. Many authorities believe that water retention may play an even more important part than the author suggests in delaying weight reduction in subjects on diets of undoubted efficacy. CHARLES H. GRAY

DYNAMICS OF FISH POPULATIONS

On the Dynamics of Exploited Fish Populations

By R. J. H. Beverton and S. J. Holt. (Ministry of Agriculture, Fisheries and Food—Fishery Investigations, Series 2, Vol. 19.) Pp. 533. (London: H.M. Stationery Office, 1957.) 126*s.* net.

THE cover jacket of this important work states that, "Many of Beverton and Holt's methods will be applicable to other living populations—animals or plants—and their theoretical framework should form part of the syllabus of teaching in agriculture, in ecology, in geography, in sociology, and in nature preservation". This is a wide claim but true enough in so far as the application of mathematics to the study of fish is ahead of its application to populations of land organisms. The book is in four parts, of which the first two are primarily theoretical representations of the four primary factors, recruitment, natural mortality, fishing mortality and growth. The application of the theoretical methods is developed in Part 3, concerned with the estimation of parameters, and in Part 4 where population models containing these parameters are used to investigate the reactions of fish populations to exploitation. The argument is here primarily concerned with North Sea plaice and haddock, but examples are taken from other fish, including perch in confined lakes, which offer particular opportunities for getting to grips with population problems.

Some readers, more interested in the practical applications than the theoretical analyses, will doubtless turn straight to Part 4, but this would do the book less than justice, because it is mainly in the mathematical treatment of the subject that new ground is broken. But, while the authors are to be admired for their enterprise after seven years of effort in compiling a work of such magnitude, bringing into prominence the role of mathematical models in ecological theory and application, their methods are not beyond criticism. The work would, indeed, have benefited by a closer revision, for some of the lucidity is lost at critical points. In the treatment of random migration, for example, the authors get into rather deep water because they do not distinguish clearly between the case where displacements (d) are constant in magnitude and that where the displacements are variable. In this way they confuse the mean value of d^2 with the square of the mean value of d, whereas in the analogy they draw with the kinetic theory, the former is twice the latter.

Proofs of essential theorems are usually given fully, but some readers may be discouraged by arrays of impressive symbols, contortions and rearrangements, where simple and lucid arguments are available. For example, pages 37 and 38 are devoted to demonstrating in a particular case that the total annual yield from a steady-state population is the same as the yield from a single recruitment class followed through its life, an obvious and general result which can be rigorously proved in a few lines without mathematics. Again, the theorem on pages 39–40 is a rather unnecessary exercise in elementary summation and integration, for it follows immediately from the more easily demonstrated theorem that an exponentially declining population grouped into year classes is geometric. There are several instances where the formulation of the problems could have been more fully stated with the exact conditions, and with their formal enunciation more prominently displayed and numbered. Some ambiguity might thereby have been avoided.

There is a useful and extensive bibliography which, however, appears somewhat deficient on certain central themes. No mention is made in the text of the classical work of Lotka on stable age-structures, and the growth equations discussed at length are attributed to Bertalanffy (1934) instead of Pütter (1920). A few references could well have been omitted, for example that to Pétart (1938), because the serious reader unacquainted with higher mathematics might misunderstand its humour.

These criticisms, however, do not detract materially from the high value of this book as a major contribution to fishery science and a source of reference and interest to workers in mathematical biology. He who thinks in terms of living organisms rather than of symbols will inevitably take some buffeting, but it is pleasing to find support given to "the tradition dating from T. H. Huxley's time, and reaffirmed by Graham, that the best management of fishing is to leave it alone until events show that intervention is necessary". There is a useful index.

NEW ACADEMIC PRESS BOOKS

Electronic Digital Computers

THEIR USE IN SCIENCE AND ENGINEERING

By F. L. ALT, *National Bureau of Standards, Washington, D.C.*

September 1958, 336 pp., illus., 80s.

THIS BOOK GIVES a complete and up-to-date survey of the techniques available for using electronic computers. It describes machines from a functional standpoint, concentrating upon aspects of interest to the potential user, and discusses all phases of problem formulation and analysis, programming, coding, and machine operation.

One of the unique features of the book is the balanced presentation of information about the capability and utility of various types of machines which should enable the scientist, engineer or other user to judge the suitability of a given machine for his particular problem.

Electronics of Microwave Tubes

By W. J. KLEEN, *Siemens & Halske Aktiengesellschaft, and Technische Hochschule, Munich, Germany*

Translated from the German by P. A. LINDSAY, A. REDDISH, and C. R. RUSSELL *The General Electric Company, Ltd., Wembley, England*

September 1958, 349 pp., illus., 72s.

THIS BOOK PROVIDES a unified treatment of the microwave tubes currently in use. A presentation of the fundamental processes involved is followed by a clear discussion of tube applications, noise, and the most important structural components—resonators, delay lines, and electron guns. The author explains, both qualitatively and quantitatively, the effects governing the operation of those microwave tubes now used in telecommunications.

A NEW SERIAL PUBLICATION

Modern Materials

ADVANCES IN DEVELOPMENT AND APPLICATIONS

Edited by HENRY H. HAUSNER, *Consulting Engineer, and Adjunct Professor, Polytechnic Institute of Brooklyn*

VOLUME 1

October 1958, 402 pp., illus., 89s. 6d.

THIS NEW SERIAL publication will serve as a valuable source of information for the engineer with broad interests, for the specialist who desires information beyond his field of concentration, and for others particularly interested in materials—executives, research and development engineers, pioneers of new materials, and students. The first volume covers the following materials and their recent developments :

Zirconium. Germanium and Silicon. Ceramics. Insulating papers for high voltages. New uses of wood as a structural material. Special glasses needed to withstand strong radiation in nuclear engineering. Synthetic rubbers. Organic and inorganic fiber materials.

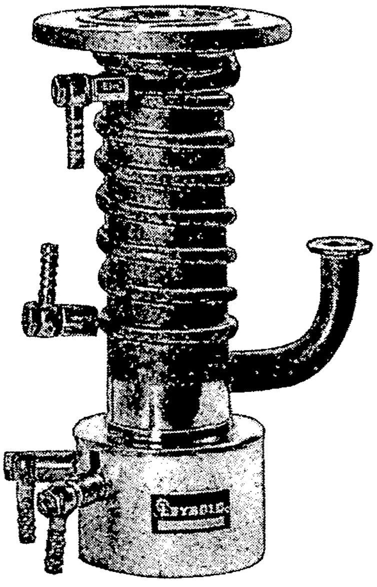
10^{-8} mm. Hg

can be attained

on industrial work



From the early days of Vacuum processing, great strides have been made to improve these techniques ; much progress and development of oil diffusion pumps have been accomplished within recent years. Constant demands from industry necessitate still further improvements. Leybold foresaw such future requirements, and started research and development work in this field of vacuum processing many years ago. They have now produced oil diffusion pumps capable of pumping speeds of 30 to 20,000 litres per second, and attaining ultimate pressures of the order of 10^{-5} mm. Hg.

For further information regarding this equipment, please send your enquiries to Leybold Vacuum Sales Ltd., Dept. N.P.

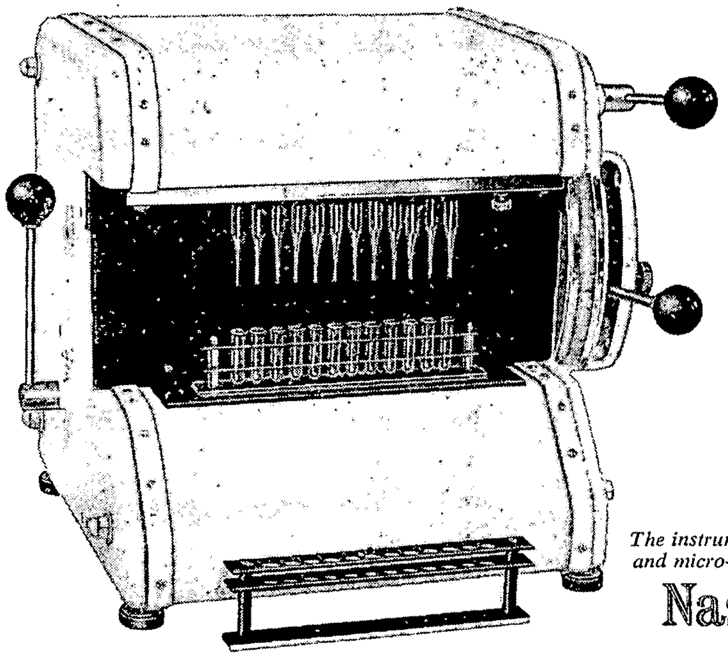
... A NEW INSTRUMENT BY NASH AND THOMPSON

THE SEROLOGICAL DISPENSER



This automatic dispenser for multiple titrations was developed at the Lister Institute of Preventive Medicine for routine serological investigations. The apparatus allows the performance of up to 12 titrations in a single operation with even less manipulation than required for a single test by conventional technique.

- **Volume range 0.01 ml to 1.0 ml.**
- **Automatic loading of up to 12 pipettes.**
- **Simultaneous dispensing from all pipettes.**
- **Accuracy better than that obtainable using Grade 'B' British Standard serological volumetric glassware.**

The instrument has possible applications in micro-chemistry and micro-biology. For further information write to:

Nash and Thompson

BIOCHEMISTRY OF CELLULOSE AND RELATED POLYSACCHARIDES*

By Dr. B. A. STONE
Biochemistry Department, University College, London

THE naturally occurring β-glucans (polymers of β-D-glucopyranose) which are listed in Table 1 form a series of structurally related polysaccharides. Many of these glucans, for example cellulose, callose and yeast glucan, are constituents of cell walls; while others, such as the *Pneumococcus* type III and *Rhizobium* polysaccharides, occur as capsules associated with cell walls. A number of them are intracellular, for example laminarin and lichenin, and may be regarded as reserve polysaccharides, while others are extracellular and of unknown significance (the β-glucans of bacteria and fungi).

Cellulose is the most abundant β-glucan; its structure and organization in the cell walls of higher plants have recently been reviewed[1]. The β-1 : 3 glucans are less well known, although as early as 1890 Mangin[2] reported the occurrence of an insoluble polysaccharide in the sieve plates of the phloem and in pollen tubes and pollen grains. The polysaccharide, which he named callose, he distinguished from cellulose by its insolubility in cuprammonium and by differential staining reactions. Callose replaced cellulose, or occurred with it, in the mycelium and fruiting bodies of many families of fungi, yeasts, lichens and some algæ. These observations have not been confirmed in any detail, but three β-1 : 3 glucans, callose, pachyman, and yeast glucan have similar properties to Mangin's callose and are found in similar situations.

Table 1. Basic Structures and Distribution of β-Glucans

	Ref.	Main linkages	Other linkages	Other monomer units	Distribution
Cellulose		1–4	—	—	Cell walls throughout plant kingdom Test of Tunicates, mammalian tissues ?
Pachyman	*a*	1–3	—	—	*Poria cocus* sclerotia
Yeast glucan	*b*	1–3	1–2	—	Cell walls of some yeasts, for example *S. cereviseae*
Callose	*c*	1–3	—	Uronic acid (2 per cent)	Sieve tubes in phloem of grape vine
Laminarin	*d*	1–3	1–6	Mannitol (2–3 per cent)	Fronds of some Phaeophyceae
Lichenan	*e*, *f*	1–3 (30 per cent) 1–4 (70 per cent)	—	—	Fronds of some lichens, notably *Cetraria icelandica*
Oat glucan	*g*	1–3 (30 per cent) 1–4 (70 per cent)	—	—	Oat grain
Barley glucan	*h*	1–3 (50 per cent) 1–4 (50 per cent)	—	—	Barley grain
Pneumococcus type III polysaccharide	*j*	1–3 (50 per cent) 1–4 (50 per cent)	—	Glucuronic acid (50 per cent)	*Diplococcus pneumoniae* type III capsule
Rhizobium polysaccharide	*k*	1–4	1–6	Glucuronic acid	*Rhizobium radicicola* capsule
Pustulan	*l*	1–6	—	—	Fronds of the lichen *Umbilicaria pustulata*
Luteic acid	*m*	1–6	1–3, 1–4	Esterified malonic acid	Culture media *Penicillium luteum*
Crown gall polysaccharide	*n*	1–2	?	—	Culture media *Phytomonas tumefaciens*

Several β-glucans with both 1 : 4 and 1 : 3 linkages are found naturally; those which occur in cereal grains are important in the germination process[3]. Thus oat glucan is located on the surface of the kernel, and during germination, it has been suggested, it is dissolved away by β-glucanases allowing access into the endosperm of enzymes concerned with the mobilization of starch[4].

Biosynthesis

Our knowledge of the biosynthesis of β-glucans has, until recently, been limited, and most of our information relates to cellulose synthesis. Analytical studies of the changes in carbohydrates in the developing cotton plant[5] and of the pathways of carbohydrate metabolism in *Acetobacter xylinum*[6] have led to the suggestion that hexose phosphate is involved in cellulose synthesis. In neither system was cellobiose utilized; thus, although transglucosylations involving the formation of oligosaccharides from cellobiose have been reported, they do not appear to be concerned in cellulose synthesis[7]. Experiments involving the incorporation of labelled carbon, administered as monosaccharides, into the cellulose of *Acetobacter* spp.[8] and of cotton[9] and wheat plants[10] have shown that the C-1 of glucose-1-^{14}C is usually retained to the extent of 60–80 per cent in its original position, although the conditions of the experiment and the physiological status of the plants greatly influence the amount of retention. These results suggest that, although some glucose can be polymerized directly into the cellulose molecule, a proportion of the monomer units of the cellulose arise by resynthesis of fragmented glucose molecules. Similar experiments have been extended to the xylan of the wheat plant by Altermatt and Neish[10]. The results suggest that the xylose units arise by the oxidation of the hexose at C-6, followed by decarboxylation.

---

* Based on two lectures delivered at University College, London, on May 5 and 12.

In cell-free systems from *A. xylinum*, prepared by Mickle disintegration[11] or glass-grinding of freeze-dried cells[12], cellulose synthesis can occur when glucose and adenosine triphosphate are added. Greathouse[12] showed that 96·7 per cent of the label was retained in the C-1 of the glucose units when glucose-1-^{14}C was used as substrate.

Uridine diphosphate-glucuronic acid and uridine diphosphate-glucose have been established as glycosyl donors in the formation of glucuronides[13] and disaccharide phosphates[14] respectively. Altermatt and Neish[10] have suggested a scheme for the synthesis of plant polysaccharides in which these types of compounds are envisaged as donors, or close precursors of donors, of the polymerized units. Their ideas are supported by the isolation, from mung bean seedlings, of a number of nucleotide glycosyl compounds and of enzyme systems involved in their formation and interconversion[15]. They are further supported by a report[16] of the synthesis of cellulose by cell-free preparations of *A. xylinum* from the labelled glucose of uridine diphosphate-glucose. Uridine nucleotide glycosyl compounds have also been implicated in the synthesis of chitin, hyaluronic acid and glycogen[17], on the basis solely of experimental evidence of the incorporation into the polysaccharide of labelled monomer supplied as the nucleotide glycosyl compound. Whether the monosaccharide of the nucleotide sugar derivative is transferred directly by a single enzymic step or whether indirectly by several steps is unknown. Until the synthesizing systems have been further examined and purified the exact role of the nucleotide derivatives will remain uncertain.

Among the β-glucans there exist representatives of many of the types of structures encountered among the polysaccharides, including unbranched chains, involving the same positional linkage type between each unit as in cellulose or two different linkage types as in lichenan, and branched chains. Among related polymers are structural types in which different monomer units are joined by linkages of the same positional but different configurational types, for example the pneumococcal type VIII capsular polysaccharide which has the repeating unit[18]:

$$\text{-}\beta\text{-}\mathrm{D}\text{-}\mathrm{G}p\mathrm{A}\text{-}(1 \rightarrow 4)\text{-}\beta\text{-}\mathrm{D}\text{-}\mathrm{G}p\text{-}(1 \rightarrow 4)\text{-}\alpha\text{-}\mathrm{D}\text{-}\mathrm{G}p\text{-}(1 \rightarrow 4)\text{-}\alpha\text{-}\mathrm{D}\text{-}\mathrm{Gal}p\text{-}(1 \rightarrow 4)\text{-}$$

(where G*p*A = glucopyranuronic acid; G*p* = glucopyranose; Gal*p* = galactopyranose), and a further type, often found among the xylans, has short side chains of xylose or other sugars attached to the main β-xylose chain.

This wide range of structural types makes any generalized statement about the mechanism of synthesis difficult, but clearly two systems would be required, the first concerned with the provision of building units of the right configuration and state of activation, which could be utilized by the second or polymerizing system and built into the characteristic structure of the polymer. We know that both these systems are under genetic control[19], and although there is some information concerning the provision of donor molecules the polymerization system for β-glucans is not understood at all. Two possibilities exist for this system. First the synthesis may be directly under enzymic control as it is, for example, in the synthesis of glycogen. However, for the synthesis of polysaccharides having different linkage types and perhaps different monomer units, the number of enzymes required would be large, their specificities restricted and often novel in character in order to direct the synthesis in a reproducible manner. The second possibility, that the synthesis is under the control of a template, has been put forward, and is considered in detail by Wilkinson in his recent review on bacterial polysaccharides[19].

It is possible to envisage the synthesis of certain polysaccharides, for example lichenan, pneumococcal type III and VIII polysaccharides (Table 1), as a polymerization of a preformed repeating unit by transglycosylation from a suitable donor. Here the sequence of units in the repeating block and their mode of linkage would be controlled either by a number of specific enzymes or by a template mechanism. Some support for this type of process is provided by the evidence, summarized by Park[20], that the nucleotide sugar amino-acid compounds, which he isolated from cultures of penicillin-inhibited *Staphylococcus aureus*, are involved in the synthesis of the bacterial cell wall.

Several of the β-glucans, including bacterial cellulose, occur extracellularly. The problem of their synthesis and appearance outside the cell is analogous to that posed by the occurrence of other high molecular weight compounds in the medium surrounding cells, for example exo-enzymes, hormones and antibodies. This problem is related in a direct way to the mechanism of the synthesis. For certain types of polysaccharides such as dextrans and levans, the synthesis can occur in the extracellular medium if suitable donor molecules are provided. For extracellular protein and probably for many polysaccharides the building units are only found intracellularly together with the system which controls the specific arrangement of the units in the polymer. This raises the problem of the selective release from the cell of the macromolecule. In the case of the bacterial cell wall complex and the capsular and extracellular polysaccharides it is possible to envisage an enzymically controlled synthesis at the cell surface (plasma membrane) or the formation there of activated units which can be polymerized extracellularly by extracellular enzymes. The problem is well illustrated by the synthesis of bacterial cellulose, where electron microscope studies indicate that the cellulose microfibrils are formed in the medium remote from the cells[21]. If this is correct then the immediate donor of the polymerized units may be found in the medium together with the transferring enzyme. Although uridine diphosphate-glucose is implicated in cellulose synthesis[16] it is unlikely to be an extracellular donor since the nucleotide portion would be lost to the cell. Some intermediate reactions appear likely. A speculative scheme based on an analogy with the formation of lactose, trehalose and sucrose phosphates[13] from uridine diphosphate-glucose and glucose-1-phosphate,-6-phosphate, and fructose-6- or 1-phosphate might involve the formation of cellobiose phosphate as an intermediate, perhaps at the plasma membrane surface. Transfer of cellobiose from its phosphate to suitable acceptors (primers) would result in the formation of cellulose molecules.

Cellobiose has something to recommend it here since it is the true repeating unit of cellulose. The isolation of an oligosaccharide phosphate and cellodextrins from the medium of actively synthesizing *A. aceti-genum* cultures is consistent with this scheme[22].

Depolymerization

The enzymic depolymerization of cellulose and other β-glucans has not been investigated at the biochemical level with the same intensity as has starch degradation. For cellulose the heterogeneous nature of the reaction system and the complexities raised by the supramolecular structure of the substrate have been the chief check to progress.

The facility with which bacteria and fungi attack cellulose contrasts with the slow and incomplete attack by cell-free enzyme preparations on organized celluloses. The difference has been argued as being due to the loss of labile enzymes in preparation[23], although the characteristic localization of the attack by bacteria and fungi suggests that the enzyme concentration at the site of dissolution, the localization of the cellulase at the cell surface in bacteria[23], and removal of reaction products might also be important factors in explaining the difference.

The effect of the supramolecular structure of the substrate on the action of cellulases has been thoroughly investigated[24], and it is clear that the attack is initially limited to the regions of low lateral association of the cellulose molecules and that any treatment of the cellulose which will increase the proportion of the less ordered regions will increase the extent of hydrolysis. Frequently the attack on the molecular chains has been shown to be by a random mechanism[25], and although there are reports that endwise attack on the chains can occur the evidence is indirect[3, 26].

Whitaker[27] has shown that a fractionated and apparently unienzymatic cellulase preparation from the mould *Myrothecium verrucaria* can hydrolyse cellulose-type molecules with lengths corresponding to a degree of polymerization of 3 and upwards. Thus a single enzyme may be responsible for an almost complete depolymerization, although the results of analysis of crude cellulase preparations from *M. verrucaria* and other fungi by a variety of fractionation procedures suggests that they are complex systems with several active components[28]. Unfortunately the components have not been obtained in a state which would allow differences in their chemistry and specificity to be clearly demonstrated.

Many cellulase preparations also contain a cellobiase and it was early suggested that cellulose hydrolysis might be a two-step process :

$$\text{cellulose} \xrightarrow{\text{cellulase}} \text{cellobiose} \xrightarrow{\text{cellobiase}} \text{glucose}$$

In some cases cellobiase activity is not limited to the disaccharide as is shown by the properties of the two fractions obtained by alumina chromatography of *Aspergillus oryzae* preparations[29]. One was termed an 'oligase' since it hydrolysed cellodextrins with degrees of polymerization 2–6 but longer chains weakly or not at all. The other termed a 'polyase' hydrolysed cellodextrins and cellulose. The activities of the two components overlapped at the cellohexaose level. A similar separation has been achieved in *Aspergillus niger* preparations by gradient elution from anion exchange columns[30]. The oligase components appear to be similar to the cellobiase reported recently to occur intracellularly in *Stachybotrys atra* mycelium and to hydrolyse cellodextrins up to degree of polymerization 11, but not sodium carboxymethylcellulose or alkali swollen cellulose[31]. A polyase component with chain length specificity resembling Whitaker's *Myrothecium* preparation has already been studied in *S. atra*[32]. The scheme of cellulose depolymerization in these fungi might then be :

$$\begin{tikzcd}
\text{cellulose} \arrow[r] \arrow[rr, bend right, dash, "\text{polyase}"'] & \text{cellodextrins} \arrow[r] \arrow[r, bend left, dash, "\text{oligase}"] & \text{cellobiose}
\end{tikzcd}$$

The synergistic action between the two components would lead to a very rapid depolymerization.

The turnover number of Whitaker's *Myrothecium* enzyme[27] reached a maximum value at degree of polymerization 4, and below this value the activity dropped off rapidly, suggesting that the upper limit for the combining site of substrate with enzyme was about four glucose units long, which closely resembles observations made with respect to the combing site of iso-maltodextrins for antibodies against dextrans[33]. *S. atra* cellobiase splits off glucose units from the end of the dextrin[34], and its activity is independent of chain length over the range of cellodextrins tested (up to degree of polymerization 11). The combining site here may only involve one cellobiose unit at the chain end, so that the length of the chain would not influence the activity until it became long enough to create difficulties in the orientation of the chain end with respect to the active site.

The depolymerization of β-1 : 3 glucans requires specific enzymes and it has been possible to separate β-1 : 3-ase activity from the poly-β-1 : 4-ase activity in *A. niger* preparations either by chromatography on calcium phosphate or anion exchange resin columns[30,35]. This linkage specificity was considered by Ploetz and Pogacar[36] in explaining kinetic data obtained with *Helix pomatia* preparations; they, however, favoured an interpretation based on the presence of a non-specific oligase and polyase which could hydrolyse β-1 : 4, 1 : 3 and 1 : 6 linkages.

Following the elucidation of the structure of lichenan we are in a position to re-evaluate some of the findings of earlier workers who regarded lichenan as another form of cellulose. It is possible that both 1 : 4 and 1 : 3 hydrolysing enzymes would degrade this polymer provided that the presence of adjacent linkages of the other type do not restrict the hydrolysis. The 'lichenase' activity of *A. oryzae* can be fractionated[37] by precipitation with ether-alcohol mixtures into a fraction with activity on lichenan but not on cellulose and two fractions with activity towards both substrates. The activity-*p*H curves for the two substrates are very different and show multiple optima. These observations can be interpreted in terms of separate enzymes, one specific for 1 : 4 linkages and the other specific for 1 : 3 linkages. However, recent observations using the separated components of the *A. niger* preparation[30] have shown that only the poly-1 : 4-ase and the β-glucosidase components hydrolyse lichenan. The presence of 1 : 4 linkages on either side of the 1 : 3 linkages apparently prevents their hydrolysis by the 1 : 3-ase.

I wish to thank Dr. E. M. Crook and Dr. S. P. Datta for helpful discussions during the preparation of the manuscript and the University of London for an Imperial Chemical Industries Research Fellowship.

VISUAL PIGMENTS IN THE COLOUR BLIND

By DR. W. A. H. RUSHTON, F.R.S.

NEARLY all colour-blind subjects confuse red and green, and the most extreme cases are dichromats, which means that they can match every colour of the spectrum with a mixture, say, of red and blue. But these dichromats are of two sharply different kinds, for the 'protanope' is insensitive to light of long wave-length and needs a very bright red light to match a moderate green, whereas the 'deuteranope' is nearly normal in his appreciation of relative brightness throughout the spectrum. Now when we plot upon the colour triangle those hues which the dichromats confuse, the points fall upon concurrent straight lines. For example, the protanope confusion loci radiate from the red corner of the colour triangle and, as Helmholtz and Maxwell pointed out long ago, this supports the view that the red 'mechanism' is absent. For this reason, protanopes are often called 'red blind'. The deuteranope lines are more nearly parallel to the red–green side of the triangle, so the name 'green blind' is less obviously applicable, and Pitt[1] has favoured the possibility suggested by Helmholtz that no sensation is lost but that red and green are fused. I have always had difficulty in grasping clearly what was the kind of thing which might in the deuteranope either be lost or fused. But now I wish to propose the view that there is both loss and fusion. What is lost is one class of cone, namely, that which in the normal is 'green-sensitive'; what is fused is the visual pigment, for the only non-blue cone which the deuteranope possesses contains the red- and green-sensitive pigments mixed together.

The pigments in the cones may be measured upon the fovea (which is rod-free) by the method of reflexion densitometry (Rushton[2]). When this is done in the red–green region of the spectrum with a protanope subject, one pigment is found. Fig. 1 shows its difference spectrum (the change in absorption after photolysis produced by shining a very bright light into the eye). The difference spectrum is the same with partial photolysis from red or from green light; hence only one visual pigment is present. If this is the pigment serving protanope vision, the curve might be expected to correspond to his daylight spectral visibility, just as twilight visibility corresponds to the absorption spectrum of rhodopsin (= visual purple).

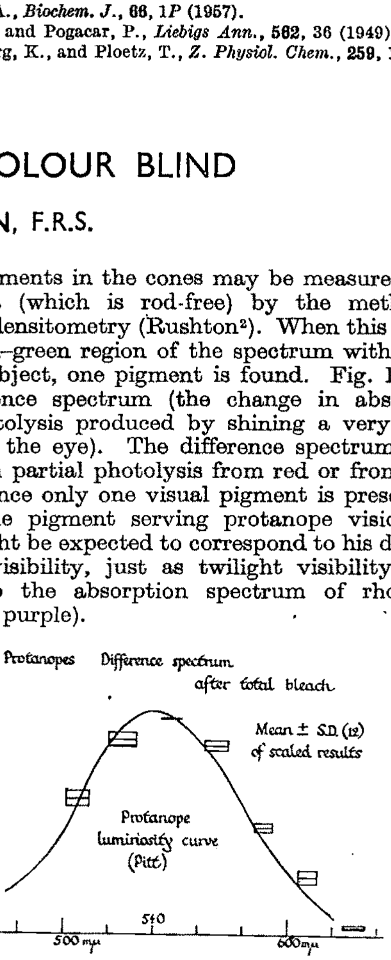

Fig. 1. Difference spectrum in the protanope, that is, the change in the logarithm of the reflectivity of the eye for light of various wave-lengths when the visual pigment has been bleached away by strong light

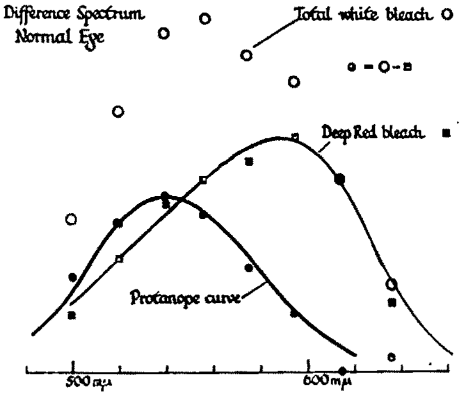

Fig. 2. Pigments in the normal eye analysed by bleaching with coloured lights. The total pigment is made up of chlorolabe and erythrolabe in the proportions shown. There is about twice as much chlorolabe in the protanope as in the normal

The curve of Fig. 1 is, in fact, Pitt's[1] protanope visibility, so it seems clear that protanopes can see only one colour in this half of the spectrum because they possess only this one visual pigment with absorption there. In contrast, Fig. 2 shows the results of partial photolysis of the normal fovea using red and green lights. This reveals two distinct pigments. One is the pigment of the protanope but in rather small amount; the other is a pigment which absorbs maximally at about 590 mμ and predominates. This latter pigment may be named 'erythrolabe' (= red taking), the protanope pigment 'chlorolabe', and the blue-sensitive pigment which does not here concern us, 'cyanolabe'. The protanope is known to have the normal number of cones in his fovea and normal acuity in his vision. Clearly, his loss is that none of his cones contains erythrolabe, but all are filled instead with chlorolabe.

A symmetrical situation would be to suppose that the cones of the deuteranope contained nothing but erythrolabe, but that is not true. Not only is the deuteranope visibility curve Fig. 4 (from Pitt[1]) very different in shape from the difference spectrum of erythrolabe, but also partial photolysis with a red or green light reveals (Fig. 3) that both erythrolabe and chlorolabe are present. Thus, the deuteranope visibility is monochromatic in the red–green, not because he lacks either of the normal pigments, but he mixes the information which separately they could give. This might be because the pigments are mixed in a single class of cone, or because the cone signals are mixed in a single class of nerve. The following two experiments point rather to the former explanation.

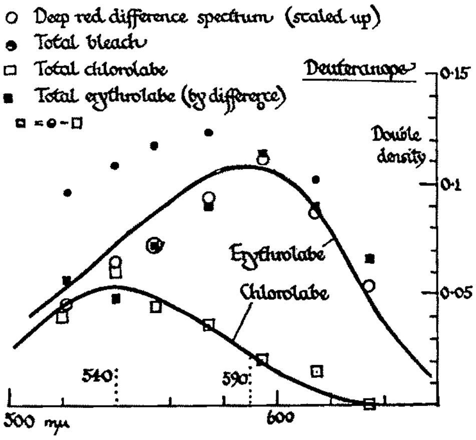

Fig. 3. Pigments in the deuteranope in correct proportions. Erythrolabe estimated by difference in total bleach (squares) and directly by bleaching with deep red light (circles)

A 4° circular field was made up of seven parallel strips of alternate green and magenta light, the blue and red of the magenta being separately adjusted by the deuteranope so that all seven strips appeared identical to him. Now a deep red field was superposed uniformly over the whole 4° of matching strips, and increased in intensity up to the point where the 4° circle was no longer visible. At no stage did the green appear different from the magenta; nor did any difference appear when a bright green field instead of a red one was uniformly superposed.

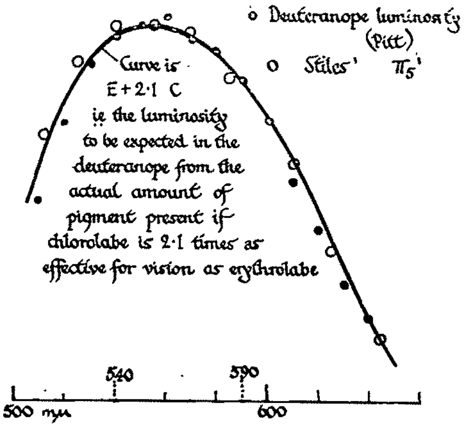

Fig. 4. Deuteranope luminosity curve (dots) from Pitt. Stiles's red sensitive mechanism π_5' (circles). The curve is the expectation from the pigments found in the deuteranope if chlorolabe is 2·1 times as effective for vision as erythrolabe. π_5' is the high-intensity form of π_5 (see Stiles, ref. 4)

When I myself looked at the circle through the strong green superposition, the green stripes were scarcely noticeable, but the magenta stripes stood out brightly. The reverse was the case when red light was superposed, and it was hard to believe that the deuteranope could find the two sets of strips equal. But his repeated settings of the red intensity for a complete match showed a divergence which was certainly less than 5 per cent when red, green or no fields were superposed.

In the second experiment, the 4° circle was half green and half magenta of the shade which exactly matched it for the deuteranope. A small point of light, either red or green, was flashed upon either one half of the field or the other, the flash being 10 msec. in duration and repeated once per sec. If the threshold for a green flash upon a red field is denoted (G/R), it was found that the ratios $(G/G)/(G/R)$ and $(R/R)/(R/G)$ were each nearly unity, and their product was exactly unity. For my (normal) eye it was about 8.

These two experiments prove that whatever is mixed in the deuteranope is mixed peripheral to that place in the retina where light adaptation occurs, and before the site where the cone signal becomes a somewhat logarithmic function of the light intensity. It appears, therefore, to arise peripheral to the place where the electroretinogram is generated, which Brindley[3] locates at the rods and cones. So, if we accept this, the deuteranope has his pigments mixed in a single class of cone. We cannot say in advance what is the relative efficacy of erythrolabe and chlorolabe in producing a nerve signal, but we may deduce it by noting how greatly the chlorolabe curve of Fig. 3 must be scaled up so that when added to the erythrolabe curve it will correspond to the deuteranope visibility curve ; the factor is about 2. The curve of Fig. 4 gives the combined effect of erythrolabe and chlorolabe so estimated, and is seen to correspond well with Pitt's visibility curve (dots).

In work extending over twenty years, Stiles[4] has investigated colour mechanisms in normal subjects by measuring the increment thresholds of flashes of one colour upon the background of another colour—a method crudely followed in my deuteranope experiment described above.

In the red–green region of the spectrum, Stiles has found two quasi-independent colour mechanisms labelled π_4, π_5, of which π_4 has nearly the same spectral sensitivity as the protanope (Fig. 1) and π_5 as the deuteranope (Fig. 4, circles). We may say, then, that the normal red–green colour mechanisms are reduced in the dichromat as follows : protanopes have only π_4, deuteranopes only π_5. But from our analysis of the foveas of these dichromats the nature of π_4, π_5 in the normal eye may now be stated. For π_4 is the response of the green-sensitive cones which contain only chlorolabe and the sensitivity of which corresponds to the chlorolabe spectrum. π_5 is the response of the red-sensitive cones which contain mixed pigments and the sensitivity of which does not correspond to the erythrolabe spectrum. The physical proportions in which the two pigments are mixed are shown in Fig. 3, but since chlorolabe is twice as effective as erythrolabe in exciting vision, we should increase its scale proportionally in all problems where we turn our analysis from pigments to sensations.

A BOREHOLE TO THE EARTH'S MANTLE?

By DR. T. F. GASKELL

Chief Physicist, Exploration Department, British Petroleum Oil Co., Ltd.

THE Mohorovičić discontinuity is the boundary between the mantle and the assorted surface rocks of the Earth, and it marks a very sharp change in the velocity with which earthquake waves travel—a jump from about 21,000 ft./sec. to 27,000 ft./sec. The mantle extends about half-way to the centre of the Earth, and encloses a core which earthquake seismic waves demonstrate to be fluid. At last year's meeting of the International Union of Geodesy and Geophysics at Toronto a resolution was passed urging the importance of drilling a bore-hole deep enough to penetrate the rock layer that lies below the Mohorovičić discontinuity.

The use of artificial earthquakes has been common practice for many years now in studying the Earth's crust. The seismic prospecting methods used to locate underground oil reservoirs tell the approximate depth and the shape of the surface of the underground layers of rock, but they do not give a firm indication of the type of rock. In order to draw an unambiguous picture of the sub-surface geology, it is necessary to follow particular rock layers from their surface outcrops, or from bore-holes. The layer below the Mohorovičić discontinuity does not come to the surface and therefore it is necessary to drill in order to find out what is the material—what chemical or radioactive properties it has—that forms the Earth's mantle.

It is found that the mantle lies at a depth of about 20 miles under the land, but that underneath the deep oceans it is only about 7 miles below sea-surface. The nearest the mantle comes to the surface of land is under oceanic islands, and here it is depressed below normal oceanic level to about 10 miles below surface. This is probably the best place to drill the hole to the Mohorovičić discontinuity.

The seismic measurements in the oceans enable estimates to be made of the thickness of sediment that has collected and compacted over millions of years on the sea-bed. As with oil-finding seismic work on land, the support of an outcrop or a bore-hole is needed to make an unambiguous interpretation of the measurements. In particular, there is a hard layer, lying beneath about 1,500 ft. of soft sediment, which could be a band of cemented limestone, or a continuous layer of volcanic rock. Beneath this again is a layer of rock which is probably the primeval ocean floor. The seismic measurements combined with analyses of volcanic material erupted from inside the Earth give some idea of what this rock might be, but they are only guesses because the exact origin of the molten lava of the volcano is not known, and in any event mixing will occur as the lava is forced upwards. A second recommendation was therefore made at Toronto—to drill a few thousand feet through the sediments that cover the three-mile deep oceans to see both what kind of rock lies beneath them and to collect samples all the way down in order to elucidate the depositional processes that have been going on in the past.

The deepest hole so far drilled is just over four miles. This hole, like most deep borings, was drilled to find oil—and it is to the oil industry that we owe most of the recent developments that have taken place in drilling. The total depth drilled is now well over a million miles, and last year in the United States alone 40,000 miles of oil wells were drilled—enough to go several times right through the Earth. Since 1927 there has been a steady increase, from 8,000 ft. to 22,000 ft., in the depth of the deepest hole.

Most modern oil-well drilling is carried out by the rotary method. It is difficult to appreciate the enormous length of pipe which is used to rotate the cutting tool at the bottom of the hole. To give an idea of the scale, a 33-ft. long wire, of 7/1,000 in. diameter, has about the same length-to-diameter ratio as a 20,000 ft. length of 4-in. drill-pipe. The cutting tool cannot be forced into the rock by pressing on such a long flexible length of pipe because the pipe would buckle. The tool is therefore driven into the rock by about 20–30 tons of extra thick pipe at the bottom of the hole, and the main length of the drill-pipe supports and rotates this bottom section. Without the heavy rigid section the drill-pipe bends, and the friction between the drill-pipe and the bore-hole almost stops the rotation; furthermore, the bit tends to go crooked. With a heavy section at the bottom, the thin drill-pipe is held in tension and the rock is penetrated quite readily. The motive power for the bit would be better at the bottom of the hole, and electric motors have been tried but without great success. It is difficult and perhaps dangerous to handle the large electric power needed, with cables that are subjected to the wear and tear of running in and out of a bore-hole.

---

* Substance of a Royal Institution Discourse entitled "Drilling Deep Holes in the Earth", delivered on June 11.

Much more commonly used is a multi-stage turbine motor, which is driven by mud and water pumped down the drill-pipe and up the space between the drill-pipe and the walls of the hole. The driving motor consists of a hundred rotor elements, which give enough power to rotate the bit many times faster than the conventional rotary systems. The friction of the drill-pipe all the way down the walls of the bore-hole limits the rotary drilling speed to about 120 rev./min. High speed of rotation means correspondingly faster rock penetration; but apart from this, light-weight drill-pipe can be used, since it only carries the weight of the turbine, and does not have to twist it around; and, since the pipe is not rotated, there is very little wear on the sides of the bore-hole. Furthermore, if the cutting bit jams on an extra tough piece of rock, the turbine will be halted but the mud will circulate and keep the hole free. With the rotary drill, jamming of the bit often means that the drill-pipe is twisted until it breaks off.

The turbo-drill has another potential advantage which has not yet been realized. Because the drill-pipe is not rotated, the turbo-drill may be made to alter course by setting the axis of the drill at a few degrees to the drill-pipe with an elbow joint. There is no reason why this process could not be in some way controlled from the surface, so that the drill could be virtually steered in any direction. This is a desirable feature, because sometimes it is necessary to drill holes that are deviated sideways; for example, when producing oil from strata below a town where drilling would be inconvenient. However, it may also be the means of speeding up rate of drilling. The rate of penetration of the drill is approximately proportional to the weight which is allowed to press on the bit at the bottom of the hole; but there is a limit to the weight because in a narrow bore-hole the weight must be distributed over a length of heavy drill-pipe. Any slight bending of the pipe causes the drill to go off course, and this effect is often accentuated by the non-uniformity of the rock strata. If the drill can be steered along the true course, then we can press harder on the drill bit while still keeping straight and thus penetrate the rock correspondingly faster.

Even if we could drill very fast indeed, we should still have to spend time every now and again pulling up all the drill-pipe to renew the drilling bit when the cutting teeth became worn, or when the roller bearings which support the toothed wheels seize up. The time taken to unscrew and stack a few miles of drill-pipe is several hours. Much engineering development has gone into improving the life of drilling bits, and a recent advance has been to construct a bit which can be folded up and pulled up the inside of the pipe on a wire, so that a replacement can be lowered to carry on drilling without any need of removing the pipe itself from the hole. It is obviously much faster to wind up a wire on a drum than to unscrew all the pipe. This device is in its infancy, and a more revolutionary approach is to speed up the actual pulling out and unscrewing of the drill-pipe by means of a double hydraulic lift. The first lift raises a length of pipe, then the second lift raises the next section while the joint is being unscrewed and the first length of pipe is being stacked away. The first lift now goes down to catch hold of a third length of pipe and so a continuous hand-over-hand process goes on. These improvements in complete automation of pipe handling will not only save time and labour on the rig, but they will also give more carefully controlled operation. Automatic drillers are in fact coming into common use, and the servo system will be even better when used with smooth hydraulic feed instead of lifting by cable. The driller's job is not made less important, however; in fact, it is becoming more skilled and technical with each new advance. One of the problems that requires expert knowledge is the behaviour of the mud that is circulated down the drill-pipe and which flows up the space between the pipe and walls of the hole, carrying with it the fragments of rock that have been cut by the bit. These chippings must be removed, and only recently have laboratory experiments shown that very rapid removal of the chippings is important. Almost as much work must be done to grind up a chip as is required to form the chip from the parent rock in the first place. For efficient drilling, then, a chip must be removed before the next cutting tooth of the bit reaches it. Special outlets are made in modern drill bits to direct a stream of mud in the right places to do this. In order to carry the rock chippings to the surface, the mud must move at a few feet per second, and in order to minimize the pump power required the viscosity of the mud must be kept down.

However, the mud has other jobs to perform, and the final mixture is usually a compromise. In the first place, the mud must not settle out into its constituent parts if left standing, because if it did, the solid material sinking to the bottom would jam the drilling tools in the ground. A mixture of ground-up shale and water separates out into its constituent parts, but the addition of a small proportion of bentonite clay maintains the shale particles in suspension and so turns the mixture into a drilling mud.

Ideally, a thin layer of dried mud cake forms over the walls of the bore-hole, and in this way preserves the mud from contamination with any soluble compounds in the rock that is being drilled. At the same time, the mud cake on the walls of the hole gives strength to resist crumbling of soft materials such as clays and shales. The weight of the mud column itself holds back the walls of the hole from caving, in much the same way as pit-props support the roofs of coal mines. A good mud has almost jelly-like properties to stop it settling and to hold up the rock chippings when drilling stops. However, it must also be easy to pump down the drill-pipe—and so must be thixotropic.

Not only does mud help to keep the walls of the bore-hole from collapsing, but it also holds back high-pressure fluids—which may be water, oil or gas—from entering the bore and causing trouble at the surface. It is unlikely that high-pressure gas will be encountered in drilling the 10-mile deep hole to the Mohorovičić discontinuity. Borings at Bikini and Eniwetok have already demonstrated that hard basaltic rock is reached at a depth of a few thousand feet, and seismic measurements have suggested that this basaltic rock continues uniformly to the 10-mile depth of the Earth's mantle. This tough basaltic rock will not need a protecting wall of mud because it is rigid enough to stand up securely on its own. The top part of the hole, which will pass through possible loose and porous coral rock, can be walled off with a strong steel casing. The main part of the hole will, however, present new problems, and in some ways these may be more akin to those met in gold prospecting than in looking for oil. Oil is not found in hard igneous rocks, and normally these are not encountered in oil-well drilling. On the other hand, bore-holes up to 6,000 ft. in length have been drilled in order to assess the potential of gold-bearing quartz strata. It is possible that water will suffice instead of mud as our circulating fluid. Some form of circulating fluid will almost certainly be needed, because although the rock may stand up without the assistance of a hydrostatic column, some cooling and lubricating of the drill bit will be required. The temperature ten miles deep is expected to be anywhere between 400° and 700° F. The pressure of the water column will prohibit boiling down the hole, but it will be necessary to cool the water when it reaches the surface. There will be no fundamental difficulty in this; in fact, it might be possible to circulate sea-water. The most likely site for the bore-hole in order to encounter the Mohorovičić discontinuity at as shallow a depth as possible will be on the edge of a coral atoll, so that sea-water will be one commodity in ample supply.

Rock-drilling in mining is often carried out using diamond bits, and the hard basalt that will be met in a deep bore-hole will probably best be cut in this way. With the high-speed rotation of the turbo-drill it might be possible to increase the normal rate of a few feet an hour to, say, ten feet an hour. At this rate it would take more than two hundred days drilling to penetrate 50,000 ft. of rock. The time taken to pull out and renew the drilling bit may be greater than this. At present rates, the complete in-and-out round trip would take more than 30 hr. with the hole at its deepest, but it may be possible to achieve a factor of three with the new automatic hydraulic lifts that are now being developed. The life of a bit in very hard rock may be only equivalent to 50 ft. of drilling, so that there will possibly be a thousand trips in and out of the bore-hole. Even with the fast automatic pull-out, the time taken will be at least as long as that spent drilling.

It is possible, of course, that a modern version of the old cable-tool type of percussion drilling with its rapid method of pulling the tools out on a wire rope may be more suited to the hard basalt rock. Pneumatic chippers have been very effective in the Sahara recently in drilling tough siliceous limestone.

It is not unreasonable to consider even more fanciful means of cutting rock when standard methods are only capable of penetrating a few feet an hour. One such method is that of burning a hole by means of a flame torch. This is used for the 50-ft. type of hole that is drilled for shot-firing in mining. Suggestions have also been made that hard tough rock might be successfully broken up by letting off explosive charges at the bottom of the hole. The loosened debris could be removed afterwards by conventional drilling methods. A small charge of an ounce or so should shatter about 6 in. of rock, and if a technique could be devised to fire a shot every few minutes a drilling rate of 10 ft. or so an hour could be achieved.

It is quite clear that considerable research work is needed to produce a workable method of drilling the 50,000 ft. hole down to the Mohorovičić discontinuity, but the type of research work required is, in fact, already proceeding as part of the normal progress of oil-well drilling and rock mining. For example, the correct operation of the diamond cutter has been shown to depend on careful control of mud circulation and weight, and a factor of ten in distance of rock penetrated before the bit wears out may soon be possible. After all, diamond is tougher than the rock it cuts, and theoretically need not wear at all. In the opinion of most of those engaged in the industry, the problem of drilling to the Mohorovičić discontinuity could be successfully tackled now if the money for the project is forthcoming. The most promising method seems to be a combination of diamond bit with turbo-drill and fully automatic lifting mechanism, using sea-water circulation. The research effort to make the necessary improvements in the various components of this scheme would undoubtedly be repaid by speeding up normal oil-well drilling, just as motor racing has helped to produce better vehicles for everyday use.

The second deep drilling problem—that of drilling a few thousand feet through the sediments of the ocean bed—could be solved at once by using the techniques developed for underwater rock sampling off the California coast. Since 1953 a programme of geological investigation of this territory has called for many borings five or six thousand feet deep to determine the rock structures that exist beneath the sea-bed. In order to make these borings, a new technique was designed which permitted drilling from a floating vessel.

The motion of the vessel is taken up by gimbal systems and by sliding sections in the drill-pipe, so that drilling can proceed except in very rough weather. The barge is anchored to six mooring buoys and drilling is commenced through a string of casing suspended from the ship and clear of the ocean floor. After a few hundred feet have been drilled, the casing is cemented to the sea-bed, together with an assembly of valves and with guide-wires connecting to the ship, so that when the drill-pipe is pulled out it can be run back into the hole again.

In one trial a 300-ft. hole was drilled in a depth of 600 ft. of water without the complication of guide wires and well-head assembly at the sea-bed. The hole was drilled until the drilling bit wore out; then, since there were no guide wires it was impossible to find the hole again after pulling out to change the bit. However, it was possible to obtain samples of the rock that was drilled by cutting cores and pulling them to the surface in a cylinder lowered inside the drill-pipe on a wire line.

It is probable that this simple 'one-shot' technique would be adequate to drill through the soft sediments of the sea-bed to determine what is the underlying hard rock layer. There is very little wear on a coring bit when drilling clay, and the one bit should be able to penetrate all the soft material and at least a few feet of any hard layer. It may not be possible to anchor the drilling barge in 20,000 ft. of water, but it is possible to anchor a marker buoy, and the barge could be kept continually in position relative to the buoy with the aid of tugs. It will be most important, of course, both to choose a place where good weather is probable, and to have good weather forecasts, because the main hazard of the operation will be the possibility of losing 20,000 ft. of drill-pipe.

There is no reason why this technique of drilling in deep water should not be extended by the use of the folding up, retractable drilling bit. If the bit can be changed without pulling the pipe from the hole, there is no limit to the depth. Experience may even show that the full Californian off-shore method is practicable, using casing cemented into the rock of the sea-bed and guide wires to the surface, in which case a very interesting possibility presents itself. The Earth's mantle is only about 10,000 ft. below the floor of the ocean, and if it is possible to drill continuously in deep water the task of reaching the Mohorovičić discontinuity would be much easier than even from a coral atoll. In the first place, it is only about 30,000 ft. below sea-level in the deep oceans, and in the second, the top 20,000 ft. is water which does not have to be drilled. The technical difficulties do not appear to be insurmountable, especially if the turbo-drill rather than rotary is used. It is probably largely a matter of gaining experience with the easier project of the two discussed, and selecting a site for the experiment where there is the essential good weather and negligible currents.

HIGH-SPEED FLIGHT

At a time when the problems of the high-speed flight of aircraft, rockets and satellites are engaging the attention of scientists and engineers, it was very appropriate that Sections *A* and *G* of the British Association meeting in Glasgow on August 28 should devote one morning to lectures and discussion on this subject.

The subject was introduced by Prof. W. J. Duncan (Mechan professor of aeronautics and fluid mechanics, University of Glasgow), who underlined some of the vital principles behind these problems, showing that with the speeds that can now be attained the sharp distinction between the flight of aircraft and that of missiles has largely disappeared. The main engineering problems of high-speed flight can be grouped under four headings: (i) aerodynamic, (ii) kinetic heating, (iii) propulsion and (iv) guidance and control.

At supersonic speeds the shock-wave system around an aircraft causes an additional resistance (wave drag). One of the most important aims of the aircraft designer is to make this drag as small as possible. The problem of kinetic heating has given rise to the misnomer, 'the heat barrier'. The air in contact with the surface of the aircraft becomes heated, the effect being greatest at the most forward parts of the surface. Thus, when the speed of flight is 700 m.p.h., the temperature rise is 49° C., and this increases as the square of the speed.

The problem of propulsion depends upon the availability, or not, of atmospheric air. At extreme altitudes where the air density is very low, jet engines (for example, turbo-jets) can no longer be used and rocket propulsion has to be resorted to. Both jets and rockets have limited operational endurance (depending on the total fuel available); but whereas a turbo-jet gives a moderate thrust for a long time, a rocket gives a very large thrust for a comparatively short time.

Conventional controls are useless at altitudes where the air density is negligible. This can be overcome by using small jets to provide the moments required. The guidance of an unmanned missile may be provided by radar or by inertia navigation.

The subject was discussed in more detail in the two following lectures, the first of which, given by Mr. L. F. Nicholson (head of the Aerodynamics Department, Royal Aircraft Establishment, Farnborough), was on "Aerodynamic Aspects of High-speed Flight".

Mr. Nicholson defined the scope of the lecture as covering speeds "upwards from that of sound", the aim being to show the extent to which supersonic flight is becoming possible. For aircraft, one of the dominating factors in favour of high speed arises from the characteristics of jet engines, the thermodynamic efficiency of which increases considerably with speeds up to about five times that of sound. This increase in efficiency will be lost unless an efficient air inlet is used, which should also give low drag and avoid unstable pulsating flows; indeed, the air intake design can be one of the most exacting tasks of the design of a high-speed aircraft.

The aerodynamic efficiency was next considered. A measure of the efficiency of an aerodynamic shape for cruising flight is the ratio of the weight of the aircraft to the engine thrust required. Thus normal well-designed subsonic transport aircraft reach aerodynamic efficiencies of about 20. If such an aircraft were made to fly at supersonic speed by merely increasing the thrust, the efficiency would drop to about a tenth of its subsonic value (due to the unsuitable shape of the wings and fuselage for flight at supersonic speeds). This can be partially remedied by designing all parts of the aircraft to achieve full efficiency when operating in the flow field induced by the remaining parts of the aircraft; this has led to swept-back cambered wings and waisted fuselages. At speeds of the order of twice that of sound, a drop in aerodynamic efficiency is best avoided by using thin wing and tail surfaces and by drawing out the fuselage into a very slender shape. The wings themselves should be of large chord and of short span, with highly swept leading edges (having a plan form similar to that of a delta wing). The flow over such wings is highly complex, with separated flows springing from the leading edges at all incidences apart from that of cruising flight.

The kinetic heating problem mentioned above is mitigated to a certain extent by the effect of radiation, which increases rapidly with increase of temperature. By flying high, temperatures can be kept down to 600° C. at speeds five times that of sound.

Looking ahead to still higher speeds, a typical flight would consist of an accelerated climb (to a speed of the order of 10,000 ft. per sec.), followed by a long decelerating glide (for ranges of 2,000–3,000 miles), the aircraft being rocket powered. Sharp points and edges on the wings would have to be avoided as they would tend to become 'hot spots'. The energy of the fuel in such flights would be almost entirely used in building up the kinetic energy of the aircraft; thus a light weight would be more important than low drag. The weight of fuel used on a typical 3,000-mile flight need only be about twice that used in a cruising flight at supersonic speed; thus hypersonic gliders are not beyond the realms of economic sense in the long-term future.

At these speeds longer ranges can be obtained in ballistic flight mainly outside the atmosphere. Here the problem of high temperatures and loads on re-entry to the atmosphere is indeed a frightening one. However, much of the kinetic energy of the motion could be diverted into heating the air in the wake rather than heating the aircraft. The best way to avoid excessive heating would be to allow the missile to follow a shallow trajectory on re-entry, using aerodynamic lift to increase the re-entry time from seconds to minutes. The increased time would allow radiation effects to dispel any excessive heating.

The final lecture, given by Mr. E. C. Cornford (head of the Guided Weapon Department, Royal Aircraft Establishment, Farnborough), was on "General Aspects of Travel at Very High Speeds with Special Reference to Rockets and Satellites". Mr. Cornford discussed the general propulsive and structural requirements of long-range ballistic vehicles and satellites, together with the problems of their guidance and control.

The flight pattern of a long-range rocket or satellite generally consists of a short period of powered flight during which the missile climbs out of the Earth's atmosphere. At the end of this stage the missile velocity ('all burnt' velocity) might be 22,000 ft. per sec. or more for a range of some 3,000 miles. The mass ratio (mass at launch/mass at 'all burnt') for such a single-stage rocket would be about 14. Thus only about 7 per cent of the initial weight of the missile is left for the payload, structure, motor, guidance and control systems, as well as any of the propellants which remain unused.

The position is much improved if a multi-stage rocket is used, that is, a missile in which two or more rockets are fired in succession, and as each burning stage is completed the empty propellant tank and propulsion unit are discarded. Thus a two-stage missile, each part having a mass ratio of 5, gives almost the same velocity as a single stage of mass ratio 25.

The main structural problem of a long-range rocket or of the launching vehicle for an Earth satellite is in the design of the integral propellant tanks, which are thin-walled cylindrical shells designed to withstand compressive end-loads (from the motor, missile inertia and drag), shear forces and bending moments (from the guidance system) and internal pressure. The thin walls of these tanks may be stabilized by internal pressurization or by mechanical means or by a combination of the two methods. The materials used need to have a high specific strength and stiffness and the ability to maintain these properties over a wide range of temperatures.

Much experience has been acquired relating to the use of liquid oxygen/kerosene systems. Possible improvements in rocket performance would be obtained by using various combinations of the oxidants (liquid oxygen, ozone and fluorene) and the fuels (liquid hydrogen, ammonia, hydrazine and the boron hydrides) to increase the specific impulse. It is questionable whether the gain in the specific impulse obtained in this way is worth the engineering effort required to make use of these liquids, almost all of which are either toxic or corrosive or liable to detonation. Recent developments with solid rocket propellants have led to specific impulses approaching those of current liquid propellants. Solid propellants greatly simplify the engineering problem, but the associated structure weights are appreciably higher. Nuclear rocket propulsion offers means of enabling space travel beyond the capabilities of conventional rockets.

The accuracy with which a long-range ballistic rocket will reach its target or with which an Earth satellite achieves a planned orbit will depend on its position and velocity at the end of its propulsion. For a ballistic rocket by far the most severe requirement is that for velocity accuracy along the trajectory at 'all burnt'. The guidance requirements for Earth satellites are likely to vary greatly with the purpose for which the satellite is intended; at present any orbit within rather wide limits is a success.

Guidance of rockets or satellites consists of the determination of the position and velocity during its powered flight, and of computing the corrections to be made to the flight path to achieve the required terminal conditions. There are, in general, two types of guidance: (i) radar measurement of position and velocity; and (ii) measurement of acceleration by means of an inertia navigator in the missile. With radar guidance systems there is the problem of noise in the system (due to variations in motor thrust, in the measuring system itself and to ionization in the rocket flame). The centre of an inertia guidance system for a long-range rocket or a satellite is the space-stabilized inertia platform, carrying three orthogonally mounted accelerometers. The main problem with inertia guidance systems is in the design of gyroscopes and accelerometers of sufficient accuracy and stability of performance. The wander of the gyroscopes can be minimized by using a flotation gyroscope. The error characteristics of the radar and inertia guidance systems are to some extent complementary. The radar system has excellent long-term stability but suffers from noise at higher frequencies, whereas the inertia system has little high-frequency noise but suffers from long-term drift.

The main function of the control system of rockets or satellites is to apply the corrections given by the guidance system to the flight path. The couples necessary to change the attitude of the missile are usually produced by deflecting the efflux jets from the main motors or by movable vanes in the jet. The control problem is complicated by any flexibility of the structure and by fuel sloshing.

In the subsequent discussion many points were raised in connexion with re-entry into the atmosphere. One speaker thought that re-entry to the denser air should be achieved as quickly as possible, the resulting heated external surface being effectively insulated from the interior of the missile. As pointed out by Mr. Nicholson, this would be doubtful from a practical point of view. Heat transfer is more severe under normal flow conditions. Powered deceleration is ruled out because of the additional fuel required. Re-entry by 'skip' would be of advantage in giving more time for the cooling of the missile but would create many problems in guidance and control.

The audience were left with the impression that there are no insurmountable technical barriers to be encountered in this field, although the practical difficulties of attaining the objectives seem formidable.

A. W. BABISTER

OBITUARY

Dr. Malcolm A. Smith

Dr. Malcolm Arthur Smith, a well-known authority on amphibians and reptiles, died at his home at Ascot on July 22 at the age of eighty-two.

He qualified M.R.C.S., L.R.C.P. in 1898 at Charing Cross Hospital and remained there for four years as house physician and surgeon before going to Siam, where he took up an appointment as medical officer to the British Legation in Bangkok. For almost a quarter of a century he practised medicine in Bangkok, during which period he acted as physician to the Court of Siam. He was one of the very few Europeans to come in contact with life at the Court and to have first-hand knowledge of its organization. On his return to Britain he wrote an interesting account of the remarkable happenings in the lives of the royal family which was entitled "A Physician at the Court of Siam", published in 1947.

His interest in herpetology gathered momentum as his zoological expeditions to the interior of Siam, Indo-China and Malay produced more rich and valuable collections, and he devoted more and more of his leisure time to the study of the Oriental species. He was an acute observer and a prolific writer, having more than a hundred publications to his credit. Most of these were based on classification and structure, although, more recently, he turned to considerations of evolutionary changes in the ear and the eye-covering of lizards, in snake dentition and in the head glands of snakes. His taxonomic studies reached a climax in an outstanding monograph on sea snakes and in the three volumes on the crocodiles and tortoises, the lizards, and the snakes, published in the "Fauna of British India" between 1931 and 1943 and after he had retired from Siam and had become an honorary associate of the British Museum. During the last decade or so of his life he committed himself to a study of the reptiles and amphibians of Great Britain, acknowledging with a wide comprehension the problems that were still unsolved or unpublished in that field. He became the author of yet another outstandingly successful book, "The British Amphibians and Reptiles", which was immediately recognized as a comprehensive and thoroughly reliable account of the structure, habits and behaviour of our British species. This is a book that is an invaluable guide to the specialist besides providing enjoyment to the layman, and it has become the standard work on the subject.

Not only an account of his scientific works shows him to have been an experienced and energetic personality, but the posts he held also indicate the zeal and devotion he gave to the advancement of herpetology. He was the first president of the British Herpetological Society from its inauguration in 1947 until 1954, recorder for the Amphibia and Reptilia section of the "Zoological Record" from 1929 until 1945 and editor from 1938 until 1949, and zoological secretary to the Linnean Society from 1939 until 1948.

A. G. C. Grandison

NEWS and VIEWS

Commonwealth Advisory Committee on Defence Science

A meeting of the Commonwealth Advisory Committee on Defence Science is to be held in Australia during October 6–28. Sir Leslie Martin, defence scientific adviser to the Australian Department of Defence, will be the general chairman of the meeting. The Australian delegation will be led by Mr. W. A. S. Butement, chief scientist of the Department of Supply, and other delegations include Dr. J. E. Keyston, vice-chairman, Canadian Defence Research Board; Dr. D. S. Kothari, scientific adviser to the Indian Minister of Defence; Dr. Mohammed Afaf, Pakistan; Dr. S. M. Naude, scientific adviser, Department of Defence, South Africa; Sir Frederick Brundrett, scientific adviser to the United Kingdom Minister of Defence, Air Marshal Sir Geoffrey Tuttle, Deputy Chief of the Air Staff, and Dr. D. H. Black, director, Armament Research and Development Establishment. New Zealand will also be represented. These meetings are held at approximately three-yearly intervals and the last was in Canada in February 1956. The object of the Committee is to promote collaboration throughout the Commonwealth in the application of science to military affairs, and the meeting will be attended by senior defence scientists and senior officers of the armed forces of the Commonwealth.

Imperial Cancer Research Fund

Dr. J. Craigie has resigned his post as director of the Mill Hill laboratories of the Imperial Cancer Research Fund so that, free from administrative duties, he can devote himself entirely to research in the laboratories. His invaluable advice on problems of research will thus continue to be available to the Fund. Dr. R. J. C. Harris is joining the Fund's scientific staff on October 1 to take up a new appointment as head of the Division of Experimental Biology and Virology. He will also be responsible (under the director, Dr. G. F. Marrian) for the general administration of the Mill Hill laboratories. Mr. A. R. Currie, at present assistant pathologist at the Royal Infirmary, Glasgow, has been appointed head of the Division of Pathology, and will take up his duties on October 1, 1959. The Fund is meanwhile giving financial support to the cancer research he is undertaking in the Pathology Department of the University of Glasgow.

Transfer of Controlled Thermonuclear Project from Harwell

It is proposed to remove the whole of the controlled thermonuclear project from the Atomic Energy Research Establishment, Harwell, to Winfrith Heath, Dorset. This change will permit the development of both fission and fusion work at Winfrith, and allow room for whatever expansion of the latter is necessary in the future. It will also provide a margin for new work as yet unseen which will undoubtedly be developed at Harwell. Winfrith Heath, which is near Dorchester, is a new site taken over by the United Kingdom Atomic Energy Authority. When first announced it was said that it would be a "second Harwell" and that it would provide scope for work on reactor development. Development of the site started in September 1957, and one of the first projects is the construction of a high-temperature gas-cooled reactor.

British Ballistic Missile fired from Woomera

A British 'Black Knight' ballistic missile was successfully launched to a height of 300 miles from Woomera rocket range on September 7. The Australian Minister of Supply, Mr. Atholl Townley, who was at Woomera to see the launching, is reported to have said that the rocket performed according to expectations. The 'Black Knight' is a purely research vehicle, and observations of the behaviour of the rocket engine, control and guidance mechanisms, together with measurements of its environment and other phenomena, were made continuously while it was in flight and relayed to ground receivers from several transmitters installed in the missile. Its behaviour during re-entry into the Earth's atmosphere was also recorded; the nose-cone has been recovered. The 'Black Knight', which is about 35 ft. long and 3 ft. in diameter, was largely developed and built by Saunders-Roe, Ltd., in co-operation with the Royal Aircraft Establishment. Static firings were made at Highdown, on the western tip of the Isle of Wight. The rocket engine was built by Armstrong-Siddeley Motors, of Coventry, to an original design of the Rocket Propulsion Department of the Royal Aircraft Establishment at Westcott.

Swedish National Committee for Physics

The ninth general physics conference of the Swedish National Committee for Physics was held at the University of Uppsala during June 3–5, 1957, and a brief report of the meeting together with abstracts of the large number of contributed papers is printed in the March issue of *Arkiv für Fysik*. (13, 251; 1958). Guest lectures were given by M. A. Melvin (Florida State University), who spoke on conservation-invariance principles and the behaviour of elementary particles, and by H. Palevsky (Brookhaven National Laboratory), who discussed the use of cold neutrons to investigate the solid state.

The majority of the contributed papers deal with aspects of nuclear physics, but there were several survey articles or lectures of general interest. H. Conde discussed the generation and measurement of high thermal radiation intensities, and E. Djurle and W. S. Rodney instrumentation for phase contrast measurements in the near infra-red. A brief survey of present-day knowledge of the elementary particles and of their transformations was given by S. von Friesen, and an account of the proposed new physics building for the University of Stockholm, which is expected to be ready for use in 1959/60, by E. Hulthen. A description of the Uppsala Ionosphere Observatory was given by W. Stoffregen. Its geographical situation is near the auroral zone and instruments for ionospheric research and an all-sky aurora camera are in operation at the observatory. The ionospheric recorders, or 'ionosondes', designed and constructed at the observatory, consist of a radio pulse transmitter and receiver, together with oscillograph units for photographic recording of the radio echoes, and they make vertical soundings of ionized layers of the atmosphere. For study at oblique incidence by means of backscatter, a rotating beam antenna is used and reflexions up to 2,000 mk. distance can be received. Since January 1957, a secondary station has been in action at Lycksele, about 500 km. north of Uppsala, and six aurora cameras are also operating at places between Uppsala and Tromsö.

Institution of Metallurgists Handbook

During the first quarter of the present century, more metal was produced and used throughout the world than during the whole of previous historic time. This growth in the practice of metallurgy demanded a body of trained and qualified metallurgists. It is, however, barely a dozen years ago since the Institution of Metallurgists was founded to meet this need. Its first object is "to advance and co-ordinate the study and science of metallurgy in all its aspects". In so doing, the Institution clearly serves the public interest, not only by certifying the scientific or industrial qualifications of its members, but also by its work, for example, in connexion with National Certificates in its subject. That a need for such an Institution existed and that it is serving the purpose for which it was founded is abundantly demonstrated by the growth of its membership, a growth which surprises even the most sanguine of its founders.

In its new form, the Year Book and List of Members for 1957–58, published for the Institution by Batiste Publications, Ltd., gives expression to the increasing prestige which the Institution enjoys and deserves. In addition to the list of officers and members and the conditions under which admission to the various grades of membership may be obtained, 75 pages are devoted to short technical articles dealing with the more important of the individual metals. In the space available these articles cannot, of course, be exhaustive, but they are very far from being superficial and the data contained are authoritative. In a foreword, Mr. James Mitchell, the president at the time this handbook was prepared, summarizes the aims of the Institution, aims which in a large measure, at any rate, have been attained, in the following words: "The Council of the Institution are most anxious that its membership should include all practising metallurgists who have the necessary qualifications, but they are insistent that a high professional standard must be maintained and they take this to include not only technical qualifications and experience but the observation of high ethical standards".

Careers in the Medical Research Council

Under the title "Technical Careers in the Medical Research Council" (pp. 31. London: Medical Research Council, 1958), the Medical Research Council has issued a brochure giving a concise but clear picture of the opportunities which are open as technical officers or technicians in the service of the Council. The Council's staff of 2,152 (only 121 of whom are part-time) comprises 224 medically qualified, 424 scientifically qualified and 91 technical officers, with 690 other technical staff, 332 maintenance and 391 administrative and clerical staff. Besides information about the general conditions of service, a brief survey of the types of work undertaken in the Council's establishments and a note on the qualifications required for entry to the various grades, the booklet includes a survey of the research programme under the main scientific headings and an alphabetical list of the Council's establishments and their addresses, which make it useful to a wide range of scientific workers.

Technical Authorship

A SCHEME of instruction and examination in technical authorship, intended for those with engineering, technical or scientific training and experience, has been drawn up by the City and Guilds of London Institute Advisory Committee with the needs of the younger entrants in mind. The examinations will also be open to practising technical authors. The regulations and syllabuses are detailed in a pamphlet, "Technical Authorship", issued by the Institute (pp. 9. London: City and Guilds of London Institute, Gresham College, 1958. 9*d*.). A four-year part-time course of instruction is envisaged and the Intermediate examination of the Institute will be taken at the end of the second year and the Final examination at the end of the fourth year of the course.

Queen Victoria Museum and Art Gallery, Launceston

THE report for 1956–57 of this progressive Museum and Art Gallery records that the renovation programme has been continued. The main projects have been the complete reconstruction of the china room, the construction of new cases in the vertebrate gallery, improvements in the lecture room and additional storage accommodation. In association with the University of Tasmania, an expedition to examine the rock markings in the Blue Tier district was undertaken. It is suggested that these are aboriginal in origin. Also in association with the local field club, an exhibition of native plants was arranged and maintained for about three months. The engagement of a temporary assistant in the geological department produced considerable development in this sphere, and many improvements were effected.

The *Records of the Queen Victoria Museum*, New Series No. 9, includes an important paper on the Van Diemen's Land Company 1825–1842 by Mr. A. L. Meston (pp. 62. 1958. Launceston, Tasmania: Queen Victoria Museum). From a study of the wool trade in Britain and the increasing inadequacy of the supply of fine wool the work proceeds to the chartering of the Van Diemen's Land Company in 1825. Its grant was for districts outside the settled areas and its power confined to producing fine wool. The colonists, however, were suspicious of absentee monopolists, and the regions of land granted were quite unsuited to raising fine-woolled sheep. Stock losses were heavy from weather, wolves and aborigines. Finally, the management were unable to overcome the natural and official obstacles, and the Company closed in 1842. The paper forms an important side-issue of the early history of the wool trade in England.

Stable Graticules

MESSRS. GRATICULES, LTD., have recently introduced a new graticule process which they term 'maXta' (for maximum stability). It has the advantage that the graticule is composed solely of a noble metal on glass; there is no gelatine or other support material. The image is firmly bonded to the glass and is extremely resistant to abrasion, obviating the necessity for a cover glass. This is an important consideration, since breakdown in graticules is often associated with the cover-glass cement. Further, the absence of gelatine means that there is no suitable substrate for fungal attack—an advantage in tropical conditions. The method is based upon work commenced by the late Julius Rheinberg. It is essentially a photographic process and is most suitable for lines on a transparent ground rather than the reverse. The technique can be applied to most of the available glasses. Three types are made having varying optical qualities. These variations are associated with the adhesion rather than with the image quality, which in each case is very good. These graticules were developed in the course of work carried out at the British Scientific Instrument Research Association, Chislehurst, Kent.

Germination of Oil-Palm Seed

THE results of an interesting investigation of the factors controlling seed germination in the West African oil palm, *Elaeis guineensis* (Jacq.) have been given by G. Hussey (*Annals of Botany*, N.S., 22, 259; 1958). It is recorded that under natural conditions in West Africa, at the average ground temperature of 25–30° C., oil-palm seed germinates sporadically over a period of years, but with continuous heat treatment (38–40° C.) 50 per cent germination of either nuts or extracted kernels occurs within a few months. The kernel comprises a small cylindrical embryo embedded in a mass of oily endosperm which in turn is surrounded by a thick testa. At germination the testa and layer of endosperm covering the distal part of the embryo are forced out as a disk-like operculum which is already demarcated in the ungerminated kernel by a circular abscission zone in the endosperm cells. The excised embryo is non-dormant and at 30° C. starts to elongate within 24 hr., either on moist filter paper or while still in contact with the endosperm. At 30° C. removal of the operculum is followed by a sluggish emergence of the embryo in air; emergence at the normal rate occurs in pure oxygen, or in air if a long period at high temperature precedes deoperculation. Fresh intact kernels remain ungerminated for at least six months at 30° C., either in air or in pure oxygen. At high temperature (40° C.) intact kernels germinate faster in pure oxygen than in air; at 30° C. the same applies only after previous treatment at high temperature. This accelerating effect of oxygen is shown to be dependent upon the progress of slow processes stimulated by high temperature. It is postulated that germination of oil-palm seed is dependent upon a minimal threshold concentration of oxygen in the embryo and that during dormancy this minimal level progressively decreases at a rate depending on the temperature.

Harkness Fellowships of the Commonwealth Fund

THE awards which have borne the title of Commonwealth Fund Fellowships since 1925 are being offered for 1959 under the title of Harkness Fellowships of the Commonwealth Fund. The Fund is an American philanthropic foundation endowed by the late Mrs. S. V. Harkness and the late Mr. and Mrs. E. S. Harkness, for promoting international understanding by providing opportunities for education and travel in the United States. Fellowships tenable in the United States are offered in separate series in the United Kingdom, in Australia and New Zealand and in Western Europe. Thirty Fellowships are offered in the United Kingdom for 1959 to men or women who have not previously worked for more than a few months in the United States, and who are graduates or have experience in government service, the professions, the creative arts, journalism, branches of business or industry. Forms of application, which must be returned before December 2, can be obtained from the Warden, Harkness House, 38, Upper Brook Street, London, W.1, from whom further details can also be obtained.

Atom School for Business Men

Nearly three hundred company directors and similar executives have been to four-day courses organized by the Isotope School, Atomic Energy Research Establishment, Harwell, during the past year. These courses are designed to give delegates information about current and possible future uses of radioisotopes in industry. The Isotope School at Harwell is running a further course during September 23–26 which is open to any company director or similar executive. There are still a number of places available on this course. Delegates will be housed at Worcester College, Oxford, for four nights and taken daily to Harwell. There will be lectures and demonstrations and visits arranged to atomic reactors, the Isotope Division Handling Hall and the Wantage Radiation Laboratories, where research is directed towards initiating the commercial use of large-scale irradiation sources. Further information can be obtained from the Registrar, Isotope School, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

International Conference on Information Processing

An international conference on Information Processing will be held in Paris during June 15–20, 1959. The conference is being organized by Unesco with the help of a group of consultants from various countries. Persons who wish to offer a paper should send the title, with three copies of an abstract of about 250 words, to their national group before October 1. Abstracts must be submitted in English or in French (or be accompanied by a translation in one of these languages). Further information can be obtained from the Honorary Secretary, Group *B*—Computation and Automatic Control, British Conference on Automation and Computation, c/o The Institution of Electrical Engineers, Savoy Place, London, W.C.2.

University News : London

Dr. R. C. Curran, senior lecturer in the Department of Pathology of the University of Sheffield, has been appointed to the University chair of pathology tenable at St. Thomas's Hospital Medical School. Mr. M. de Burgh Daly, Locke Research Fellow of the Royal Society in the Department of Physiology at University College, has been appointed to the University chair of physiology tenable at St. Bartholomew's Hospital Medical College. Dr. P. L. Pratt, lecturer in physical metallurgy in the University of Birmingham, has been appointed to the University readership in physical metallurgy tenable at the Imperial College of Science and Technology. Dr. A. M. Cook, senior lecturer in pharmaceutics at the School of Pharmacy, has been appointed to the University readership in pharmaceutics tenable at that School.

Scientific Film Association

Owing to the continued growth in membership and the consequent increased demands on its services, the Scientific Film Association has moved to new offices in 3, Belgrave Square, S.W.1. These premises have been made available by Aslib, and it is anticipated that this closer relationship will introduce the work of the Scientific Film Association to many who are concerned with documented information of all kinds.

Announcements

Dr. Joseph Auer, head of the Department of Anatomy, Faculty of Medicine, University of Ottawa, has also been appointed assistant director of the Division of Medical Research, National Research Council of Canada, from August 1.

Prof. H. C. Darby has been appointed to fill the vacancy in the membership of the National Parks Commission created by the retirement of the Rev. H. H. Symonds.

Mr. N. S. Billington, who has been head of the National College for Heating, Ventilating, Refrigeration and Fan Engineering since February 1950, has resigned as from August 31, 1958, to take up the appointment of director of the Heating and Ventilating Research Council. Dr. David R. Scott, at present a senior lecturer on the staff of the Royal College of Science and Technology, Glasgow, has been appointed to succeed Mr. Billington.

The Corday-Morgan Commonwealth Fellowship for the year 1958/59 has been awarded to Miss Rama Bhattacharya, who has, since January 1957, been junior research fellow of the Council of Scientific and Industrial Research, India, at the University College of Science, Calcutta. It will be tenable in the Department of Chemistry, University College, London, under Prof. Sir Christopher Ingold. The Fellowship is not offered for the academic year 1959/60.

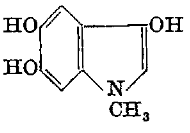
A conference on "Food and Farming : a Survey of Problems and Remedies" will be held, under the auspices of the Association of Agriculture, at the London School of Economics, on September 27. Further information can be obtained from the general secretary, The Association of Agriculture, 53 Victoria Street, London, S.W.1.

The Scottish Group of the Nutrition Society is holding a symposium on "Nutritional Hazards caused by Radioactive Contamination of Foods" in Edinburgh on September 27. Those interested, who are not already members of the Society, are invited to write for further particulars to Dr. J. Davidson, the Rowett Research Institute, Bucksburn, Aberdeenshire.

The Institute of Personnel Management is to hold a conference on "The Individual and the Organization in Modern Society" at Harrogate during October 10–12. Further details can be obtained from the Institute at Management House, 80 Fetter Lane, London, E.C.4.

A meeting of the Photoelectric Spectrometry Group will be held in Courtauld Hall, Queen Elizabeth College, Campden Hill Road, London, W.8, on October 17, at 2.30 p.m., when three papers dealing with spectropolarimetry will be read. Further information can be obtained from Mr. K. A. Macdonald, Arbury Works, 56, Arbury Road, Cambridge.

Erratum. In the communication entitled "Reduction of Adrenochrome with Ascorbic Acid", by Dr. R. A. Heacock and Miss B. D. Laidlaw, in *Nature* of August 23, p. 526, there is a misprint in formula V (adrenolutin) ; it should be



THE COUNCIL FOR NATURE

THE inaugural meeting of the Council for Nature took place in the rooms of the Zoological Society of London on July 12, when Lord Hurcombe delivered his presidential address. He emphasized that the Council has no intention of taking up an impracticable or hostile attitude towards developments necessary for the economic interests of Britain, but that nevertheless the preservation of natural life and resources is entitled to a high place in a civilized and highly populated country. Secondly, he felt that schemes involving biological devastation should be more seriously investigated than they sometimes were, and that necessity rather than convenience should be borne in mind. Further, while local and specialized societies are often engrossed with their restricted interests, they have a duty towards securing a state of public opinion that considers the interests of naturalists realistically. Indiscriminate chemical warfare on pests and river pollution by effluents show that a full realization of the problems has certainly not yet been achieved.

Lord Hurcombe appealed to all interested societies and authorities to join in making a concerted attempt to preserve the remaining resources of natural life in Britain, and gave assurances that the Council would encourage the establishment of Nature reserves and naturalists' trusts, and would co-operate so far as possible with the Society for the Promotion of Nature Reserves and with the Council for Field Studies. Finally, he announced that the Council for Nature is to have the honour and stimulus of the patronage of H.R.H. the Duke of Edinburgh. The meeting then proceeded to consider items of essential business. The draft constitution was adopted and the members of the executive committee elected.

The chairman, Sir Landsborough Thomson, described the functions of the three sub-committees that the Council proposes to set up. One will deal with conservation problems; another will concern itself with education; and the third will be for publicity and public relations.

Mr. Aubrey Buxton, honorary treasurer, then dealt with the proposal that a magazine should be published for the Council. This would certainly not be a house journal, but a popular journal aimed at a wide public with an interest in many aspects of natural history and the countryside.

One of the most important aims of the Council is to create a new interest in the countryside among school children and organized youth groups. Some of this interest could be guided into practical work in Nature reserves and other conservation projects.

After the business meeting, Mr. Tony Soper spoke of the work of the Natural History Unit of the B.B.C., explaining, with illustrations, many of the problems involved in filming and making sound recordings for natural history programmes. The secretary of the Council, which is now supported by more than a hundred societies, is Mr. D. J. B. Copp, 41 Queen's Gate, London, S.W.7.

THE ROYAL SOCIETY OF CANADA

THE seventy-sixth annual meeting of the Royal Society of Canada was held at Edmonton, Alberta, during June 2–4, under the presidency of Prof. Thomas W. M. Cameron, of McGill University. In celebration of the jubilee of the foundation of the University of Alberta under the presidency of the late Dr. H. M. Tory in 1908 and because Edmonton is the gateway to the north-west of Canada, a symposium was held on the "Potentialities of the North-West". The subject was introduced by Dr. C. H. Mackenzie, president of the Atomic Energy Control Board and past-president of the National Research Council of Canada. He was followed by Dr. R. F. Legget, director of building research, National Research Council, who discussed transportation and housing possibilities; by l'Abbé Antoine d'Eschambault, who dealt with the historic background; by Prof. W. C. Wonders, of the University of Alberta, who considered geographical problems; and Prof. D. Rawson, of the University of Saskatchewan, who spoke on biological problems of the region. The symposium was closed by Dr. D. B. Turner, Deputy Minister of Recreation and Conservation and Commissioner of Fisheries, British Columbia, who summed up the possibilities of northern British Columbia, the Yukon and the Mackenzie Valley.

Sectional symposia were also presented on "Oceanography" and on "Physical Methods in Organic Chemistry". In addition, papers were read in the various Sections of the Royal Society of Canada: mathematical, chemical, physical (under the presidency of Dr. Leo Marion); geological (under the presidency of Mr. H. C. Rickaby); and biological (under the presidency of Dr. W. R. Campbell).

Prof. Cameron's presidential address was on "The Evolution of Evolution". He noted that in the year of the founding of the University of Alberta, the Linnean Society had awarded Alfred Wallace a medal for the paper read fifty years previously, simultaneously with Charles Darwin, when the two naturalists introduced the subject of evolution by natural selection. Wallace had named the subject "Darwinism" and had left the field free for Darwin to develop further. As a result, Wallace's part was largely minimized or overlooked. Another man whose work had been misinterpreted, mistranslated and, to a great extent, overlooked, was Lamarck—discredited by Cuvier in France and both misrepresented and ignored elsewhere. It seemed obvious that few workers had read his original "Zoological Philosophy"; if they had, his part in the evolution of the theory would be much better understood. Other workers whose views had played a part in preparing the way for Darwinism were Buffon and Erasmus Darwin—the remarkable grandfather of Charles—as well as the geologists Hutton and Lyell. Prof. Cameron quoted Darwin's own views on this: "Species have been modified during a long course of descent chiefly through the natural selection of numerous successive slight, favourable variations: aided in an important manner by the inherited effects of the use and disuse of parts, and in an unimportant manner (that is, in relation to adaptive structures whether past or present) by the direct action of external conditions and by variations which seem to us in our ignorance to arise spontaneously. . . . I am convinced that Natural Selection has been the most important but not exclusive means of modification".

Prof. Cameron said that while Wallace gave a stimulus to Darwin to publish "The Origin of Species" in 1859, much of its immediate popularity was due to Herbert Spencer and Thomas Huxley. The theory of natural selection stated a fact and did not attempt to explain how the variation arose—merely how it was used. The kernel of the theory lay in heredity, and Mendel, almost simultaneously with the Wallace–Darwin papers a century ago, was laying the foundations of genetics to explain how interspecific variation was inherited. However, much still remained to be discovered, particularly the part played by the cytoplasm of the germ cells in producing major fundamental changes. The year 1958 marks not only the centenary of the Wallace–Darwin publication and the bicentenary of the tenth edition of the "Systema Naturæ" of Linneus, but also the century of the publication of the first description of Neanderthal man which directed attention to the fact that the evolution of man himself is the most important aspect of the theory.

Civilization represents the modern evolution of man and civilization has to grow and change, or decay and die. Growth and change do not always mean progress; in fact, the history of life on Earth shows that more often they lead to extinction. Man is the first and only animal, however, that has some control over his environment. Used wisely, that control can lead to progress.

"The constitution of the heavenly bodies and the structures of the atom," said Sir Oliver Lodge, "are in a sense elementary compared with the problems which confront those who would ascertain and disentangle even the material aspect presented by living things."

The following were elected to office in the Royal Society of Canada for the year 1958–59: *President*, M. Pierre Daviault; *Vice-President*, Dr. H. G. Thode; *Honorary Secretary*, Col. C. P. Stacey; *Associate Honorary Secretary*, Dr. Guy Sylvestre; *Honorary Treasurer*, Dr. N. E. Gibbons; *Honorary Editor*, Dr. G. W. Brown; *Honorary Librarian*, Dr. W. Kaye Lamb; *Editor of 'Studia Varia' for* 1959, Dr. T. W. M. Cameron; *President of Section* 3 (*Mathematical, Chemical and Physical Sciences*), Prof. G. M. Shrum; *President of Section* 4 (*Geological and Allied Sciences*), Dr. L. S. Russell; *President of Section* 5 (*Biological Sciences*), Dr. N. H. Grace.

FODDER PLANTS

A SYMPOSIUM on fodder plants, organized by the Institute of Plant Breeding of the Polish Academy of Sciences, was held at Poznań during June 25–27. It was attended by delegates from the U.S.S.R., the United States, Sweden, Germany, Hungary, Czechoslovakia and the British Commonwealth, who later had the opportunity of inspecting the experimental fields at the research stations of Baborówko and Przebedowo, near Poznań, and a number of other experimental stations farther afield. One of the most striking features of the symposium was that, although several of the contributions dealt with clovers, lucerne and other fodder plants, the great majority were devoted to lupins. Many areas of Poland have light sandy soils where lupins are among the few leguminous species that can be grown successfully. Mineral fertilizers seem to be in rather short supply, so that lupins are encouraged for the sake of their beneficial effects on soil fertility. Some are used as green manures. The greatest attention is, however, focused on the so-called sweet lupins which, owing to their low content of bitter alkaloids, can be used as fodder for livestock. The sweet lupins were first produced in Germany, and during the war years breeding work was carried out with them at Puławy in Poland. From this material hundreds of promising selections have now been produced and were demonstrated in the experimental fields. The most successful are selections of *Lupinus luteus*, which are more reliable in yield, but promising sweet selections of *L. albus* and *L. angustifolius* were also shown. The selections were distinguished by greater vigour and yield of green matter, earlier maturity, freedom from pod shedding, greater palatability, smaller seeds and other features.

By a group of investigators working at various research stations in Poland an intensive study has been made of the chemical structure of the lupin alkaloids, and many of the Polish contributions to the symposium dealt with these studies, largely based on analysis by paper chromatography. Several alkaloids not hitherto identified have been found, one of which has been named angustifolin, having been detected first in *Lupinus angustifolius*. On the basis of the structure of their alkaloids E. Nowacki (Poznań) has classified the genera of the family Genisteae, and the conclusions correspond with many arrived at on purely morphological features. Thus, *Laburnum* never contains spartein, its alkaloids, consisting of cytisin, methylcytisin and laburnin, whereas many *Cytisus* species contain spartein but no laburnin. The separation of the two genera is thus justified. *Sarothamnus* contains no cytisin and should be excluded from the genus *Cytisus*. In the same way the relationships between the species within the genus *Lupinus* have been assessed, and the grouping arrived at is borne out by considerations of the composition of the anthocyanins, flavones, proteins and fats and corresponds to the differences in chromosome number where these exist. A triple hybrid of (*L. ornatus* × *L. mutabilis*) × *L. douglasi* was described, some of the segregates being distinguished by high yield and earliness.

Papers presented by delegates from abroad included a review of the use of polyploidy in plant breeding in Sweden by A. Hagberg (Svalöf), who referred to three tetraploid clovers, one of rye and one of swede turnip produced at Svalöf; Ulva red clover exceeds the diploid by 11 per cent in yield, and Sirius swede exceeds the diploid by 16 per cent while having a dry-matter content of 12 per cent.

N. A. Majsurjan (Timirjazev Academy of Agriculture, Moscow) spoke of experience with sweet lupins in the Soviet Union. *Lupinus angustifolius* and the sweet forms of *L. albus* and *L. luteus* have large seeds, and efforts are being made to produce forms with small seeds. Sweet forms of *L. polyphyllus* are of interest, particularly on account of their earliness. From a cross of *L. angustifolius* × *L. linifolius* a promising form has been selected which combines the small seeds of the latter species with a plant type similar to *L. angustifolius*, together with earliness and low alkaloid content. Evidence was presented in support of the view that the species *L. mutabilis*, which crosses easily with the small-seeded American species such as *L. ornatus*, is itself a hybrid.

H.-J. Troll (Müncheberg) spoke of experiments on producing sweet forms of *L. luteus* and *L. angustifolius* which ripen uniformly and do not shed their seeds. Some useful mutants have been obtained by irradiation with X-rays, and latterly also with cobalt-60. J. Hackbarth (Max Planck Institut, Scharnhorst) spoke of mutants characterized by vigorous growth and others with a thermoneutral developmental reaction, suitable for growing in northern latitudes or for late sowing. W. Plarre (Hadmersleben) referred to experiments in which such thermoneutral types could be detected by vernalization and described a promising new hybrid produced by this means which is being released for cultivation in Eastern Germany. Several speakers referred to impressions that the sweet strains, especially those free from shedding, are inferior in yield, but evidence was given by Prof. Hackbarth and others to show that this is not necessarily so.

Contributions dealing with topics other than lupins included an account by N. Clark (Agricultural Experiment Station, Madison, Wisconsin) of the co-operative research on forage production leading, after twenty-five years of work, to the production of the first synthetic lucerne variety, Vernal. A detailed description was given by E. Åkerberg (Svalöf) of the development of the seed-production industry in Sweden, as a result of which Sweden now produces most of her own seed of the main species of forage plants. Among the achievements of plant breeding, special mention was made of the red clovers resistant to *Sclerotinia* and eelworm, the winter-hardy lucernes, the persistent and high-yielding white clovers, the polyploid clovers and strains with greater leafiness, better powers of a series of improved grass recovery and superior quality.

R. Focke (University of Rostock) mentioned some tetraploid red clovers that are 36 per cent better than diploid strains in fodder yield. They are, however, 20–40 per cent lower in fertility. Certain other speakers mentioned the same difficulty, though in certain cases a fairly satisfactory seed set had been obtained; thus a figure of 20 per cent was mentioned by H. Kress (Germany) for certain tetraploid red clovers, and up to 89 per cent in tetraploid white clover after selection for short corolla tube.

P. S. Hudson

SCIENTIFIC RESEARCH AND DEVELOPMENT IN EAST AFRICA

THE annual report of the East Africa High Commission for 1957*, in which a foreword by the chairman, Sir Evelyn Baring, records the tenth anniversary of the establishment of the High Commission, notes also the concentration of its eight departments in new headquarters in Upper Hill Road, overlooking the city of Nairobi. Almost half the report deals with the research and scientific services. The East African Agriculture and Forestry Research Organization records steady progress, and stress is laid on the value of the work on the full utilization of the inadequate or unreliable rainfall and on the chemistry of soil fertility. A statistical study of published data on the digestibility of the protein fraction of fodders indicated that all ruminants have the same ability to digest the protein in fodders, and that its digestibility in normal fodder depends solely on the protein level in the ration and not on its sources. The East African Veterinary Research Organization records further significant advances in the growth in cell culture of various types of rinderpest, Rift Valley fever and sheep pox, and the agar double diffusion precipitation test has been applied in the diagnosis of pleuropneumonia, while a co-operative project with visiting scientists from the United States is concentrating on African swine fever in the first instance.

The East African Fishery Research Organization has made extensive studies on the food of commercially important species, but its hydrological observations, which require extension, have been handicapped for lack of a vessel which can be used for prolonged journeys across Lake Victoria. The East African Marine Fisheries Research Organization has been provided with a new research ship, and the Organization has been able, in consequence, to extend its programme to include tuna long-line fishing on a greater scale. Under the East African Trypanosomiasis Research Organization different methods of collecting *G. pallipedes* have been studied in south-east Uganda as part of a fundamental study of the density of flies and their infection-rates. Work on trypanosome immobilization and complement-fixation tests continued, and methods have been developed for deep-freezing *T. brucei*, *T. rhodesiense* and *T. congolense* for up to seven months with solid carbon dioxide. Work on the trypanosomes in the fly has shown that the infection does not reduce the life of the fly. Physiological studies on tsetse flies are also reported.

Much of the work of the East African Institute of Malaria and Vector-borne Diseases is advisory; but its research activities have included studies of the life-cycle of anopheles, an experiment on the control of malaria in the Parc–Tavetz area, and bilharzia studies. The East African Virus Research Institute was concerned mainly with the natural history of the insect-borne virus diseases in East and Central Africa, but clinical work has now been started. The East African Institute for Medical Research continued its work on the absorption of foodstuffs, and the pilot scheme for eradicating filariasis on Ukara Island. The main work of the East African Leprosy Research Centre during the year was the therapeutic trial of diphenylthiourea started in 1956. The Lake Victoria Fisheries Board reports evidence that the species *Tilapia zillii* may help to offset the annual dearth of fish in the off-season of July. The East African Industrial Research Organization continued to investigate the artificial drying of Arabic coffee and is now providing an advisory service in fuel technology, while its work on the development of a sound technique for producing vitreous white ware pottery is emphasized. Expansion of the East African Metrological Department is planned and promising results were obtained in work on the reduction of evaporation of water from reservoirs with a film of cetyl alcohol.

The Desert Locust Survey maintained close co-operation with the Anti-Locust Research Centre and extra officers were recruited to deal with the re-invasion of the Somali Peninsula. Promising results were obtained in initial field aerial spraying tests with diazinon, and aerodel (11 per cent gamma-BHC) proved ideally suited for spraying locusts even in bad weather over difficult terrain. By the time the locusts started to breed in October 1957 the Survey had concentrated 30 officers and 125 vehicles in the Somaliland Protectorate and eastern Ethiopia and provided 65 vehicles in Somali with adequate supplies of bait and insecticides. Concern is expressed at the almost continuous nature of the threat since the War, but reference is also made to the development of international co-operation under the Food and Agriculture Organization of the United Nations and elsewhere.

SOIL ZOOLOGY

A COLLOQUIUM on "Research Methods in Soil Zoology", organized by the Soil Zoology Committee of the International Society of Soil Science, was held at Rothamsted Experimental Station during July 10–14, by permission of the director (Sir William Ogg) and the director of the Department of Entomology (Dr. K. Mellanby) and with financial assistance from Unesco and the Shell Petroleum Co., Ltd.

Although the titles of the 95 papers give an impression of great diversity, it is possible to distinguish certain themes which emerged from the papers and from the discussions and which are worth reporting to a wider public. This is so largely because the papers, grouped into five sections, were made available to members beforehand and (with a few exceptions) were not read at the conference; instead, the section recorders provided reviews of the papers, and these were then followed by really useful discussions, during which a reasonable amount of time was available for consideration of the most worthwhile topics.

Perhaps the most constantly recurrent theme was one which belongs most appropriately to Rothamsted, namely, the nature of the relationship between the biologist and the mathematician; this was introduced in the first section on "Methods of Sampling and Analysis". As J. G. Skellam pointed out, the relationships between the structures of the two subjects are indirect, and it is not always appreciated that it is the biologist and not the mathematician who must provide the working hypotheses that are to be tested by the application, for example, of statistical methods to his data. If the biologist simply provides a mass of undigested figures the mathematician is scarcely to be blamed if he erects his system of tests on a mathematically convenient but biologically unrealistic set of hypotheses. This theme was amply illustrated by speakers on such diverse topics as the spatial distribution of soil fauna, the analysis of species composition of communities and the measurement of efficiency of extraction methods.

A variant of this theme, on which the views of speakers proved irreconcilable, was the roles of experiment and statistical analysis in biological science. Whereas Dr. K. Mellanby and Prof. Kühnelt (Vienna) were advocates of the elegant laboratory experiment resulting in the production of few, but reliable, data and the support of field work wherever possible by laboratory experiment, Dr. J. E. Satchell (Merlewood) and others were strongly in favour of the use of mathematical analysis on selected field data, and Prof. M. Ghilarov (Moscow) and Prof. Franz (Vienna) were of the opinion that such methods are usually inappropriate owing to imperfect sampling methods and patchy distribution of soil organisms. Although there must obviously be room for great differences in approach to so wide a field, it was evident that the use of statistics as an analytical tool is still rather limited outside the English- and French-speaking countries and that the need for the kind of work that we associate with the name of Rothamsted is still great.

A most useful contribution to this liaison work was the first paper by M. J. R. Healy, whose survey of basic statistical techniques concluded with sections on non-random distributions and the use of transformations in variance analysis. Prof. H. R. Debauche (Louvain) as recorder of this section reviewed a wide range of topics in which mathematical techniques are appropriate to ecological studies, including, especially, the analysis of production and energy flow and the delimitation of communities. J. G. Skellam introduced a mathematical analysis of the use of extraction methods for population estimation with emphasis on the effect of extraction-rate and population heterogeneity on accuracy. Also from the Nature Conservancy D. D. Mountford introduced a new method for classifying species records into associated groups; this method was devised for the analysis of records obtained by J. E. Satchell covering between 50 and 100 species at each of ten sites, and is noteworthy, first, because an estimate of statistical significance is provided, and secondly, because this was the first occasion at the Colloquium on which the use of an electronic computer was reported, the distribution data for the species having been fed to the machine at Rothamsted on punch cards. Evidently this is but the beginning of a further field of application for these machines, for the next paper, by Dr. R. E. Blackith (Imperial College of Science and Technology), acknowledged their value in a discussion of the fields of application of multivariate analysis. Further contributions to this section were concerned with the study of distributions of aggregated populations along more or less familiar lines, Dr. R. D. Hughes (Wellesbourne) introducing a novel technique for estimating mean radius and frequency of patches of high density.

The second section, on "Extraction Methods", was reviewed by the recorder, Dr. P. W. Murphy, and was followed by demonstrations of apparatus and techniques. Some of the methods were already familiar, but new features introduced in the twenty-four papers or in the discussion included an extension of the use of suction methods for collecting ground surface arthropods, a machine for brushing microscopic species from leaves, the use of marking techniques both for population estimation and for assessment of the accuracy of extraction methods, the improvement of the extraction efficiency of Tullgren funnel methods by the control of humidity and the use of solar heat for funnels in large-scale faunal survey work in the U.S.S.R. Reports of comparative trials of different methods served to underline the variations in efficiency which occur when the same method is used on different animal groups, on different soil types and even in the hands of different operators.

The third section, on "Systematics and the Ecologist", was summarized by Dr. H. Gisin (president of the Committee), who was especially concerned with the relationships between the ecologist and the taxonomist when co-operating in the study of the more 'difficult' groups such as the mites and the Collembola. The taxonomist has the right to receive material in good condition, to be spared preliminary sorting and to make decisions about publication on taxonomic matters, in exchange for which the ecologist can expect rapid determination of selected material and the provision of keys at least to generic level. When determinations to species are required, a fruitful field of co-operation is provided because large ecological differences may accompany only small variations in morphology. There were differences of opinion about the value of reference collections, at least when these are uncritically used, and about the extent to which keys should be carried to the level of species, and should be limited to single countries or natural faunistic regions. Prof. Franz announced a scheme for the uniform publication of a series of keys to the European soil fauna under his editorship and published in Berlin, and Dr. G. O. Evans (British Museum, Natural History) described another scheme for a European key to genera of mites in collaboration with Dr. J. Balogh (Budapest) and Dr. K. Strenzke (Wilhelmshaven). A number of taxonomists present made pleas for correct mounting and preservation methods (not all of which were compatible) and described suitable techniques.

The fourth section, on "Soil Zoology and Pedology", was introduced by Prof. H. Franz (Vienna), who insisted on the need for close liaison between the two subjects. The influence of the past history of a soil on its present fauna and characteristics and the nature of the distinction between the aquatic and aerial components of the soil fauna were discussed. The papers in this section included two methods for studying the nature and rate of decomposition of the latter.

The fifth section, on "Laboratory Techniques", was ably reviewed by J. d'Aguilar (Versailles) and included twenty-nine papers on three main fields, namely: (1) the study of soil by sectioning, microscopical and photographic techniques; (2) the use of numerous special culture methods for different groups of soil animals; and (3) methods for studying metabolism of soil animals by means of radioisotopes and of a special micro-respirometer. Further details of techniques were provided in the discussion together with some sobering examples of ways in which unforeseen factors can cause faulty experimental results; in this way the complementary roles of laboratory and field work were vividly illustrated—at least to those not too far committed to one or other school.

The value of the colloquium was much enhanced by the efficient organization of the secretaries, Dr. P. W. Murphy (Rothamsted) and J. d'Aguilar (Versailles), and owed much to the wise and sympathetic chairmanship of Dr. Mellanby and his colleagues. The discussions throughout were recorded, and translation was ably supplied between English and German. The proceedings, including the discussions, are to be published this year by Messrs. Butterworths in two volumes, the first covering Sections 1–4, and the second containing the papers in Section 5 which are thought likely to have a wider appeal.

A. MACFADYEN

BRITISH COAL UTILIZATION RESEARCH ASSOCIATION

THE annual report* of the British Coal Utilization Research Association for 1957 includes a brief review of the Association's research work. The major objectives during the year were to help in bridging the gap between suitable coal supplies and energy requirements and assisting the implementation of the Clean Air Act. The development of a small-pipe system for central heating was substantially completed, as was work on the formulation of procedures and the design of equipment for measuring the emission of grit and dust; an automatic particle counter and sizer developed by the Association is now in commercial production. Tests at Leatherhead on the stationary locomotive boiler were also completed and further experimental work with the model furnace-tube plant has reduced the unaccounted heat loss to about 2–3 per cent Increased attention is now being given to automatic control of firing appliances and, with the increasing use of small coal in such equipment, to the study of grit and dust catchers. An improved method was devised for controlling the air distribution through the fuel beds of chain grate stokers for boilers of the shell type, and methods of alleviating the rapid corrosion at the cold end of a boiler, particularly of air heater surfaces, have also been investigated.

Laboratory studies continued on the mode of release of chlorine, alkalis and sulphur from coal up to 1,500° under shock heating conditions, and further tests have shown that the potential tar yield of the coal as defined by the Gray King Assay provides a good basis for comparing coals for tar content. Problems associated with the production of fuel or synthetic gas in gasifiers operating at high pressures and temperatures, at which the ash is in the form of liquid slag, were also investigated with the view of utilizing small low-rank coal.

Basic research included investigations into the chemical basis of the plastic softening of coals, with the view of better control of coking properties; studies of the fundamental reactivity of graphite towards oxidizing gases in relation to porous structure; and on the solvent extraction of a medium-rank coal with tar oils, using ultrasonic extraction equipment, to produce a smokeless fuel with coal extract as a by-product. A further step was taken towards the establishment of the absolute significance of measurements of surface areas of coals and carbonized coals by the heat of wetting method. A list of reports and published papers is appended.

JUBILEE OF ESKDALEMUIR OBSERVATORY

ESKDALEMUIR Observatory, the geomagnetic and meteorological observatory in a remote situation in north-east Dumfriesshire, was founded on May 11, 1908. It was established because the westward extension of electric tramways from London rendered the magnetic observations at Kew Observatory insufficiently exact for many purposes. Compensation of £10,000 was paid by the tramway company to the National Physical Laboratory, under which the geomagnetic work at Kew Observatory then came, and this money was used to build Eskdalemuir Observatory. The site is reputed to have been chosen by placing a coin on a map so as not to intersect any town or railways within 10 miles. Eskdalemuir came with Kew under the control of the Meteorological Office in 1910.

The history of geophysical work at Eskdalemuir and plans for the future are given by the present superintendent, Mr. M. J. Blackwell, in the May 1958 number of the *Meteorological Magazine*.

The Observatory has been throughout a first-order geomagnetic and meteorological observatory. Until 1925, in which year the seismographs were transferred to Kew, it was also a seismological observatory.

Three sets of magnetic instruments, each set recording horizontal force, declination and vertical force, are now in use. The three sets are of different sensitivity and traversing rate and serve different purposes. The magnetographs are in a non-magnetic underground house, the temperature of which is thermostatically controlled. Absolute observations of the magnetic elements are also made, of course. It is interesting to note that the declination of 18° W. in 1908 has now decreased to less than 11° W. The records of the magnetographs are analysed at the Observatory, work which continually becomes more complex.

In meteorology and atmospheric physics, extensive work is done in climatology, solar radiation, atmospheric ozone and atmospheric electricity, to mention but a few of the main activities. The apparatus for measuring precipitation includes a variety of standard and experimental rain and snow gauges. Special observations undertaken during the present International Geophysical Year are chemical sampling of air and rain-water, measurements of evaporation and investigation of the vertical distribution of ozone.

The situation of the Observatory has meant that accommodation has to be provided for all the staff, with associated domestic workers, who form a small community—in early years a very isolated one.

Mr. J. Crichton, a former superintendent of Eskdalemuir, wrote in the *Meteorological Magazine* in 1950 : "So far no encroachment by artificial (magnetic) disturbance has taken place". In expressing good wishes to the Observatory for its next fifty years, we can hope that the happy state of absence of artificial disturbance will continue.

FORESTRY POLICY IN BRITAIN

THE Minister of Agriculture, Fisheries and Food, Mr. J. Hare, in a statement on forestry policy in the House of Commons on July 24, said that the Government had reviewed the position and decided to fix the planting programmes of the Forestry Commission for periods of ten years at a time. For 1959–63 the programme would be about 300,000 acres, and for 1964–68 it would be reduced to about 235,000, when the Commission's existing plantations began to come into full production. The size of subsequent programmes would be reviewed in five years time in the light of the national needs, and in deciding when planting should take place, special attention would be paid to the upland areas, particularly in Scotland and Wales, where expansion of forestry would provide needed diversification of employment and important social benefits.

The Government proposed to continue its support to private woodland owners, particularly through the dedication scheme, but the present maintenance grant of 5*s*. 6*d*. per acre would be replaced by a management grant of 18*s*. per acre on the first 100 acres, 12*s*. on the next 100 and 7*s*. per acre on the rest. The planting grant would be continued, but for approved woodlands would be raised from one half to the full rate per acre. These increased grants are contingent on the formation of an effective woodland owners' association, as recommended by the Watson Committee. The grants for thinning and poplar planting would be terminated, and, in reviewing in future years the level of grants, trends in receipts for private woodlands as a whole as well as trends in costs would be considered. Eventually—in twenty to thirty years time—the level of assistance needed by way of planting and management grants should become nominal. The system of felling licences would be continued ; a statutory instrument would eliminate the need for a licence for fellings in dedicated woodlands, and in general licences would be freely granted for other fellings, subject to the existing arrangements for consultation with planning authorities. Normally, licences would be conditional upon restocking. In reply to questions, Mr. Hare said that the Forestry Commission would consult the woodland owners' organizations in assessing trends in receipts and costs, that his Department was working in the closest possible co-operation with the Secretary of State for Scotland and the Forestry Commission and that there would be no interference with the assistance now given by the Commission to farmers who sought to replant scrub land and land covered with bushes and trees.

LEAF AREA AND PASTURE GROWTH

AGRICULTURISTS are ultimately concerned with yield per unit area of land, and it is the aim of plant physiologists interested in agricultural problems to attempt to analyse the causes of variation in yield. In a recent review entitled "The Significance of Leaf Area in Pasture Growth", by C. M. Donald and J. N. Black of the Waite Agricultural Research Institute, Australia (*Herbage Abstracts*, 28 ; 1958), it is pointed out that of the chief physical factors limiting yield, water and nutrients have received more attention than light, particularly in pasture studies. Under field conditions the amount of light falling on a pasture is not controlled by man, nor is it subject in any particular locality to the same degree of annual fluctuation as is rainfall. When light is the only limiting factor the ultimate capacity of a species to produce dry matter depends on the degree to which a community of such plants can exploit the light falling on it. This will depend on the habit of the plant. The yield, therefore, will depend to a great extent on the area of photosynthetic tissue which is able to intercept light energy, that is, the leaf area. Consequently, the important factor is the relationships of leaf surface to soil surface, and this was first put on a quantitative basis by D. J. Watson in his concept of 'leaf area index', which is defined as the leaf area per unit area of land. This index has the virtue of being a measure of the whole crop rather than of individual plants.

Watson postulated that the greatest dry-matter production would occur when the maximum leaf area coincided with seasonal conditions most favourable for photosynthesis. The development of a leaf system capable of intercepting a high proportion of the incoming light energy is of great importance in the growth of field crops ; at values of the index below this level, maximum growth cannot occur. On the other hand, at higher values mutual shading of leaves may result in a reduction in growth-rate of the crop.

The limited number of determinations of the leaf area index of pastures suggests that these values may considerably exceed that of crops, and it is suggested that there may be several reasons for this. First of all, the types of plants which have been selected by man to sow pastures for his animals are those with heavy leaf production. A second major aspect affecting the index is the greater number of plants per unit area in pastures compared with crops.

The authors emphasize that the application of the concept of leaf area index to problems of pasture growth is of great potential value. They stress that provided other conditions are optimum light is the only limiting factor determining productivity of a pasture and that efforts to increase production beyond the high levels already recorded in some environments may be in vain unless this limiting factor is fully appreciated. With these concepts clearly in mind the object in pasture management will be to pass as rapidly as possible to the optimum leaf area index for pasture growth and then to hold the pasture at this level. Any operations which delay this process, such as early grazing when the index is low, will substantially delay attainment of the optimum and may have an effect on subsequent production quite disproportionate to the amount removed. Other aspects of pasture production capable of analysis in terms of leaf area index are pointed out.

LABORATORIES IN GRAMMAR SCHOOLS

THE inadequate provisions for science teaching in grammar schools have been brought out only too clearly in the answers to a questionnaire which was sent to some 2,000 schools about a year ago*. The 472 schools from which data were considered are widely distributed over the whole of England and Wales, with a slight bias towards London and the surrounding counties.

These schools contained about 25,000 pupils, of whom 90·9 per cent took some science. This is a reassuringly high proportion which does not vary much between the extremes of 86·5 per cent in independent boys' schools and 93·9 per cent in the small grammar schools. How much science was studied was not indicated, and, for many pupils, the time devoted to science may be very small, perhaps only one or two periods a week.

Almost all pupils do some science in the first three years of their secondary courses. In the fourth year the percentage figures drop a little, and in the fifth (O-level) year, about 90 per cent of pupils are taking science, although not all of these will offer science subjects in the O-level examination. The dropping of science in the fourth and fifth years may occur because subject specialization is already starting, or it may be because sufficient teachers or laboratories or both are not available.

In the sixth form there is a considerable fall in the percentage of pupils taking some science. This is particularly marked in the girls' schools, being only 47 per cent in the two categories of grammar schools having 300–399 pupils and 400–549 pupils, 44 per cent in the 500–699 category, and 39 per cent in the larger schools. The corresponding figures for boys' schools are 66, 60, 61 and 65 per cent.

Expressed as a percentage of total sixth-form numbers, the figures for girls' schools are about half of those for boys' schools. Since the sixth forms in girls' schools are smaller than in boys' schools, the number of girls specializing in science is less than half the number of boys.

These results support the view that girls' schools could be an important source of the increased number of scientists required in industry, in Government departments, for teaching and for many other purposes.

One question required each school to state its total number of laboratories and other rooms having a special connexion with the teaching of science. Using the standards framed by other responsible bodies, namely, the Ministry of Education and the Committee of the Industrial Fund for the Advancement of Scientific Education in Schools, the figures reveal the inadequacy of existing provisions.

---

* *School Science Review*, 39, No. 139 ; June 1958.

More than half of the schools which appear to be adequately provided with laboratories by Ministry of Education standards are girls' and mixed schools which, if considered by the higher standards the Ministry adopts for boys' schools, would not be regarded as adequately provided.

An attempt was also made to discuss the existing provision for laboratory assistance. Out of 362 maintained grammar schools answering the questionnaire, 92 (25 per cent) have no laboratory assistance at all. 31 (8·6 per cent) have only part-time help, and 78 (22 per cent) have only one junior assistant. 85 per cent are not adequately provided with laboratory assistance.

The amount spent each year on science in grammar schools is revealing. 144 out of 337 maintained grammar schools, that is, 43 per cent, had less than 8*s*. per year per pupil taking science. At one extreme an independent boys' school has £3 10*s*. per year for each pupil taking science, while one direct-grant boys' school has £2, and one independent girls' school has £1 15*s*. 9*d*. The highest figure shown by a maintained boys' school is £1 8*s*. 8*d*., and for girls' £1 5*s*. 10*d*. At the other extreme, one boys' grammar school has only between 1*s*. 3*d* and 3*s*. 6*d*. annually for each pupil taking science. Financially, as in other respects, girls' schools are, in general, considerably worse off than boys' schools. It appears that the schools with less than 10*s*. yearly for each pupil taking science (that is, about half of the grammar schools) are being subjected to conditions which are frustrating and inimical to the work they are called upon to do.

Schools were invited to make general comments concerning difficulties encountered in science departments. 256 schools gave seventy different reasons for the difficulties they faced. Among reasons given which received considerable support were: (*a*) accommodation generally cramped and crowded (79); (*b*) sharing accommodation or using another school's science laboratories (13); (*c*) laboratories too small (14); (*d*) no advanced laboratories (16); (*e*) laboratories widely dispersed—in several cases by a mile or more (19); (*f*) no preparation rooms (10); (*g*) out-of-date and/or ill-designed laboratories (14); (*h*) laboratories used as form rooms (21); (*i*) much science teaching in class-rooms (16); (*j*) serious shortage of storage space (22); (*k*) inadequate finance, lack of capital grant, etc. (33); (*l*) shortage of staff (28); (*m*) lack of suitable qualified staff (28); (*n*) too many young and inexperienced staff (14); (*o*) staffing ration not generous enough, time-table too heavy, etc. (17); (*p*) classes far too large (24); (*q*) no laboratory assistants (22); (*r*) inadequate or poor quality laboratory assistants (48).

MEDICAL RESEARCH IN INDIA

THE Technical Report of the Scientific Advisory Board, published annually by the Indian Council of Medical Research (pp. xii+290. New Delhi: Indian Council of Medical Research, 1957. Rs. 1), has primarily included detailed reports of work done under all the research schemes financed by the Council during the year. The report for 1956, as a measure of economy, contains only short abstracts of work done under research schemes financed during 1955–56. Of these, 52 relate to chemical research, 5 each to cholera and leprosy, 9 to malaria and other arthropod-borne diseases, 10 to tuberculosis, 3 to venereal diseases, 4 each to environmental hygiene and sanitation and to industrial health, 16 each to maternal and child health, to nutrition, to physiology and pharmacology, 1 to mental health, and 7 to virus diseases. Besides details of the Scientific Advisory Board and its Advisory Committees and Sub-committees, the report includes lists of papers published by workers of the Indian Council of Medical Research in 1956 and of those dealing with work done under the auspices of the Council and published in 1956.

From this array of papers it is almost impossible to select any for particular mention, but as of more general scientific interest reference may be made to the electron microscopic investigations on micro-organisms under Prof. K. N. Das Gupta at the Institute of Nuclear Physics, Calcutta; to the leprosy research work under Dr. N. Mukerjee at the School of Tropical Medicine, Calcutta; the laboratory and field investigations at the Malaria Institute of India, Delhi, on resistance in houseflies and mosquitoes to chlorinated hydrocarbon insecticides and the comparative efficiency of different insecticides against mosquitoes; on the control of *W. malayi* filariasis in Travancore–Cochin with diethylcarbamazine; the studies in vitamins, proteins and fats at the Nutrition Research Laboratories, Coonoor; and on the biosynthesis of ascorbic acid by the Nutrition Research Unit at the University College of Science and Technology, Calcutta.

The Indian Council of Medical Research has also issued a review of the progress made in the research projects it sponsors covering the whole of the period 1950–57 (pp. v+169. New Delhi: Indian Council of Medical Research, 1957). The survey is intended to convey some idea of the philosophy and approach of the Indian Council of Medical Research to the development of medical research in India, the contribution being made towards public health and the direction in which it is moving. Among the features stressed in the introductory review are the measures taken against malaria, filariasis, leprosy, plague, tuberculosis, trachoma and preventable blindness; the new outlook on cholera and venereal disease and malnutrition and virus disease. The survey gives a concise and readable account of the organization of medical research in India, both in diverse fields of research, between different institutions and of the balance between fundamental and applied research. Besides this section, which displays a vision, determination and resource on which the Council and Government of India are to be highly congratulated, there is a section on progress in selected fields, while a further section on the year ahead, as well as the concluding section, show that the Council is fully alive to the factors upon which effective scientific work depends and is seeking to provide the scientist, not simply with the institutions and equipment, but also with the conditions of service in which he can give of his best.

PARTITION OF PROTEINS IN LIQUID POLYMER–POLYMER TWO-PHASE SYSTEMS

By Dr. PER-ÅKE ALBERTSSON

Institute of Biochemistry, University of Uppsala

THE behaviour of proteins in liquid two-phase systems has been of increasing interest because partition chromatography and counter-current extraction have been shown to be useful tools for the fractionation of protein mixtures, thus complementing adsorption chromatography and zone electrophoresis[1,2].

Suitable two-phase systems for proteins are difficult to construct, mainly because (*a*) most proteins are easily denatured or precipitated by the organic solvents usually used for preparing phase systems, and (*b*) proteins are macromolecules and have, therefore, a general tendency to concentrate only in one phase, that is, one obtains either very high or very low partition coefficients. When, as sometimes happens, two proteins concentrate in different phases this is, of course, an advantage since it leads to large separation factors. If, however, two proteins go to the same phase it is difficult to apply partition chromatography or counter-current extraction for their separation.

To overcome these difficulties, phase systems have been used which are made by mixing water, salt, and organic solvents soluble in water, like alcohol, glycol ethers, etc.[1–7], in such proportions that the composition is near the plait point. Such systems dissolve many proteins and give finite partition coefficients. Near the plait point the partition coefficient is, however, extremely sensitive to small changes in the composition of the phase system which, in turn, is sensitive to variations in the temperature. The composition and temperature must therefore be controlled very carefully.

This communication describes some results that have been obtained when proteins are distributed between two-phase systems composed of water and two high polymers soluble in water. Such systems have been used for the fractionation of cellular particles[8]. Ref. 8 also contains references to the theory and experiments on polymer–polymer phase separation in general. It is well known that when two different polymer solutions are mixed, phase separation occurs, even at low concentrations of the polymers. Of the two phases thus obtained, one contains almost all of one polymer and the other phase almost all of the other. Both phases, however, usually contain between 80 and 99 per cent of water, depending upon the type of polymer used and its mean molecular weight.

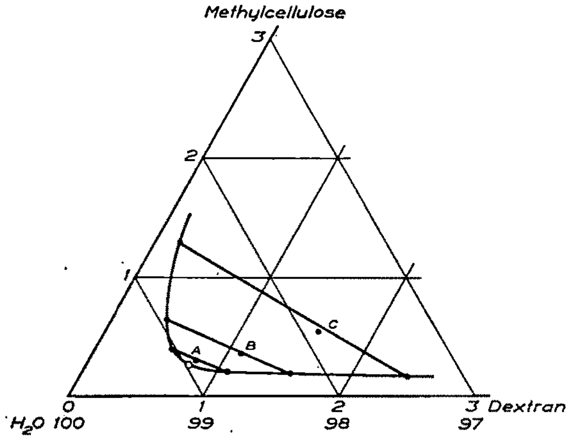

Fig. 1. Part of a phase diagram with tielines for the system dextran–methylcellulose–water at 20° C. ○, plait point. The compositions of *A*, *B* and *C* have been used for the determination of the partition coefficients of proteins (see Table 1). (Composition per cent w/w.)

Fig. 1 shows a typical triangular phase diagram of a polymer–polymer system, dextran, methylcellulose and water. (The dextran was obtained from AB Pharmacia, Uppsala: intrinsic viscosity, 0·68; weight average molecular weight, 1,800,000; number average molecular weight, 280,000. The methylcellulose, 'Methocel', was obtained from the Dow

Table 1. The Partition Coefficient of certain Proteins in the Two-phase System Dextran–Methylcellulose–Water at the following three total Compositions (w/w) (compare Fig. 1):
A, 0·80 per cent dextran, 0·30 per cent methylcellulose, 98·90 per cent buffer + protein; *B*, 1·10 per cent dextran, 0·36 per cent methylcellulose, 98·54 per cent buffer + protein; *C*, 1·58 per cent dextran, 0·54 per cent methylcellulose, 97·88 per cent buffer + protein
Protein content in the total system 0·1–0·2 per cent w/w

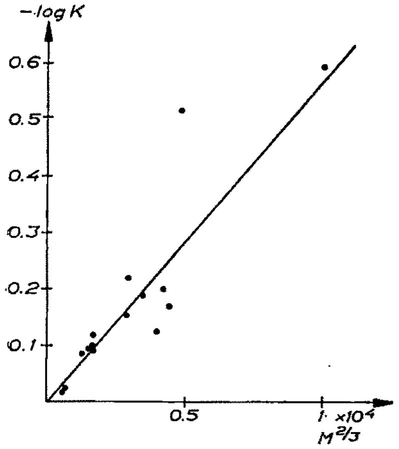

Fig. 2. Relation between partition coefficient (K) and the molecular weight (M) of the proteins in system G (compare Fig. 1 and Table 1)

Chemical Co.: 31·5 per cent methoxyl; viscosity, 4,149 centipoises; average molecular weight, ~150,000.) Other systems such as dextran–polyvinyl alcohol–water and dextran–polyethylene glycol–water have already been described[8]. As Fig. 1 shows, one phase (bottom) consists mainly of dextran and water, and the other (top) of methylcellulose and water, except very near the plait point.

Three compositions, represented by the points A, B, C on the phase diagram (Fig. 1), were selected for further study.

The partition coefficient of a number of proteins was determined in these systems in the following way. One gram of an aqueous protein solution previously dialysed against buffer (see Table 1 for concentrations) was added to 9 gm. of a mixture of dextran, methylcellulose and buffer in a separating funnel so that the desired composition as indicated in Table 1 was obtained. The mixture was allowed to equilibrate in a thermostat at 20° C. and was shaken by turning the funnel upside down about fifty times. The phases were then allowed to separate overnight. Portions of the top phase and the bottom phase were then collected, weighed and diluted appropriately for the determination of the protein content.

As indicated by the results in Table 1, all proteins, except pepsin, concentrate in the dextran-rich phase.

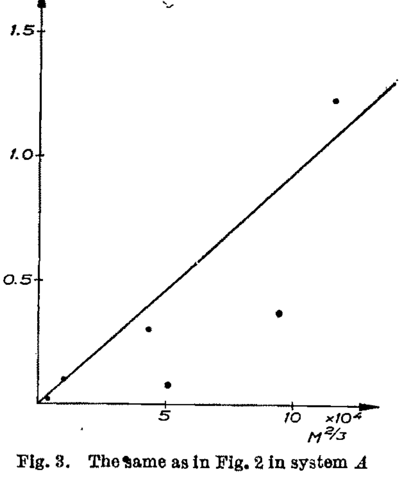

Fig. 3. The same as in Fig. 2 in system A

Even far from the plait point most of the proteins have measurable finite partition coefficients between 0·1 and 1. This differs considerably from the results obtained with low molecular weight phase systems[4–7].

There is a significant correlation between the partition coefficients and the molecular weights of the proteins (Table 1). The conditions were not exactly similar for all the proteins, so the partition coefficients cannot strictly be compared, but the general tendency is obvious. The pH and ionic strength also affect the partition coefficient, but not to the same extent as the molecular weight, provided the protein molecule is stable. If the protein molecules aggregate, or dissociate, due to changes in pH or ionic strength, these latter factors will, however, affect the partition coefficient considerably.

The results in Table 1 (see also Figs. 2 and 3) are compatible with the theory of the partition of macromolecules in two-phase systems originally worked out by Brönsted[9]. He derived the following relationship between partition coefficient (K) and the molecular weight (M) of 'isochemical' substances:

$$\log K = \frac{\lambda}{RT} \cdot M$$

where λ is a constant characteristic of the phase system and the type of substance. If the partitioned molecules are globular, like most proteins, M should be replaced[9] by $M^{2/3}$.

A closer comparison with theory will be postponed until more experimental results are available and a wider range of partition coefficients have been determined.

It seems that analysis of the partition in this phase system would be a simple way to obtain at least a rough estimate of the molecular weights of proteins. For example, the determination of the partition of enzymatic and hormonal activity and substances of low molecular weight in crude mixtures like cell homogenates could give information as to the size of the particles to which these activities and substances are attached.

The proteins seem to dissolve without denaturation. The enzymes retain at least 90 per cent of their activity. With hæmocyanin, however, precipitation was occasionally observed at low pH values.

The system dextran–methylcellulose–water is comparatively insensitive to changes in temperature. The time necessary for the two phases to separate is about 12, 6 and 1 hr. for the systems A, B and C, respectively. The top phase of system G is rather viscous, and small drops of the bottom phase remain in it for some time, but this introduces no serious error in the determination of partition coefficients between 0·1 and 1. In both systems, B and C, the two phases can be separated in a few minutes by centrifugation at low speed, for example, 2,000 g, without taking special precautions to control the temperature.

Table 2. PARTITION OF PROTEINS IN THE SYSTEM DEXTRAN–POLYETHYLENE GLYCOL–WATER WITH DIFFERENT FRACTIONS OF THE POLYMERS

The proteins are partitioned with finite partition coefficients but in favour of the phase indicated in the columns under the proteins. Compare ref. 8, Table 4. *PEG*, polyethylene glycol

Phase system. (Nos. indicate mol. wt. of polymers)	Hæmoglobin	Serum-albumin	Phycoerytrin	Phycocyan
Dextran 20,000–*PEG* 6,000–7,500	dextran	dextran	dextran	dextran
Dextran 1,800,000–*PEG* 6,000–7,500	,,	,,	*PEG*	*PEG*

Other polymer systems are also able to dissolve proteins. In the system dextran–polyethyleneglycol–water, the distribution of some proteins is highly dependent upon the molecular weight of the two polymers. Thus, the partition coefficient can be shifted from less than one to greater than one by replacing one of the polymers by another fraction of the same polymer with a different molecular weight (Table 2). This is analogous to the distribution of particles in similar phase systems as described earlier[8].

An obvious difficulty of this method of protein separation is that the phase system components cannot easily be removed by dialysis. However, this could possibly be overcome by zone electrophoresis or adsorption of the proteins, on an ion exchanger or calcium phosphate, for example.

Further work is in progress, and a detailed report will probably be published later.

I wish to express my thanks to Prof. A. Tiselius for stimulating interest and support. The work has been aided by grants from the State Council of Technical Research.

FORMS OF PYRIDINE NUCLEOTIDES IN RAT-LIVER MITOCHONDRIA

By Dr. J. L. PURVIS

Laboratory of Physiological Chemistry, University of Amsterdam

IN connexion with studies to determine whether mitochondrial isocitric dehydrogenase is a linked nucleotide with di- or tri-phosphopyridine, it was necessary completely to deplete the mitochondria of their pyridine nucleotides. The depletion was followed by determining the amounts of oxidized and reduced di- and tri-phosphopyridine nucleotides by specific enzymic, fluorometric methods[1] applied to acid and alkali extracts of mitochondria after different times of incubation. Fig. 1 describes an experiment in which the mitochondria were incubated with 40 m*M* phosphate (Fig. 1 *A*) and with 1·9 m*M* adenosine diphosphate + 33 m*M* nicotinamide (Fig. 1 *B*). Fig. 1 *A* shows that the depletion of diphosphopyridine nucleotide consists of two phases: first, the conversion of reduced diphosphopyridine nucleotide to its oxidized form; and secondly, destruction of the oxidized diphosphopyridine nucleotide. The oxidation of reduced triphosphopyridine nucleotide occurred somewhat slower but in a similar manner. Nicotinamide inhibited the destruction of the oxidized nucleotides (Fig. 1 *B*).

Fig. 1 also shows that during incubation with 40 m*M* phosphate or 1·9 m*M* adenosine diphosphate the content of diphosphopyridine nucleotide reacting with yeast alcohol dehydrogenase increased to a value above the total of both oxidized and reduced nucleotides at zero time. The extra diphosphopyridine nucleotide must be derived from some precursor. Since the increase occurred after incubation with phosphate, adenosine diphosphate or 2,4-dinitrophenol but not with adenosine triphosphate, it is probably due to the breakdown of a compound containing diphosphopyridine nucleotide rather than to a synthesis of that nucleotide. Moreover, pyridine nucleotide synthesis is localized in the nucleus[2]. A similar increase in the total of oxidized and reduced triphosphopyridine nucleotides during the incubation indicates that the increased diphosphopyridine nucleotide does not result from a conversion of triphosphopyridine to diphosphopyridine nucleotide. The fact that the compound containing diphosphopyridine nucleotide yields this nucleotide on addition of phosphate, adenosine diphosphate or 2,4-dinitrophenol but not adenosine triphosphate strongly suggests that it is connected with oxidative phosphorylation. In fact, it has the properties expected of a diphosphopyridine nucleotide compound (DPN $\sim I$) which has been postulated as an energy-rich intermediate of oxidative phosphorylation[3,4]. The concentrations of phosphate, adenosine diphosphate or 2,4-dinitrophenol necessary to give a half-maximal appearance of diphosphopyridine nucleotide from its reduced form and the energy-rich intermediate were 3·5 m*M*, 185 μ*M* and 4·5 μ*M*, respectively. The half-maximal concentration of adenosine diphosphate in the presence of 2 m*M* phosphate was 70 μ*M*. These K_m values follow the same order as in oxidative phosphorylation.

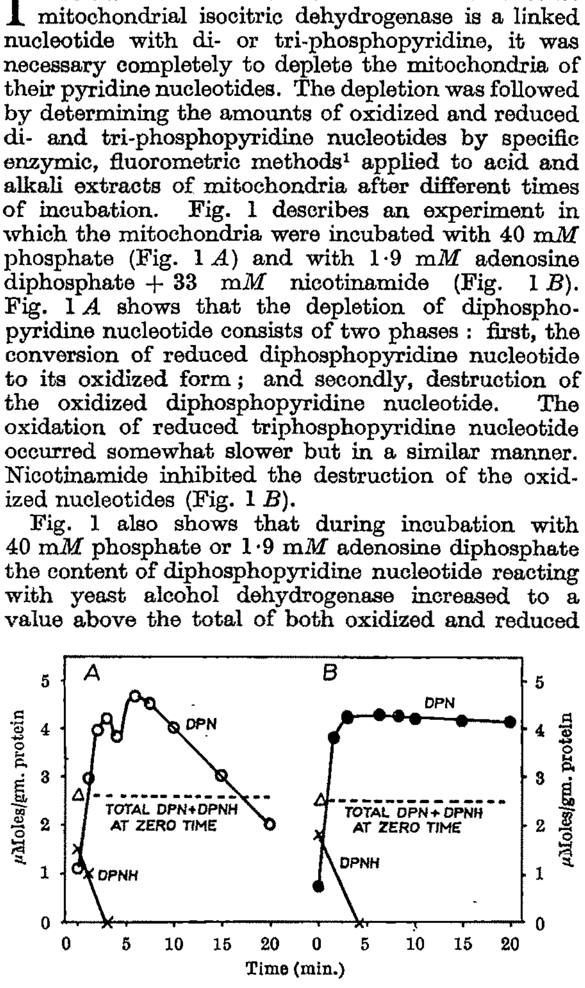

Fig. 1. The mitochondria were incubated at 30° C. with 40 m*M* phosphate (*A*) and with 1·9 m*M* adenosine diphosphate + 33 m*M* nicotinamide (*B*)

The amounts of the various forms of the pyridine nucleotides in mitochondria are given in Table 1. Recovery experiments with added reduced di- and tri-phosphopyridine nucleotides ranged from 90 to 110 per cent. Thus the increase in total pyridine nucleotide after incubation is not due to an under-estimation of reduced di- and tri-phosphopyridine nucleotides.

Eisenhardt and Schrachinger[5] have estimated the amount of high-energy compounds present in liver mitochondria, non-respiring owing to lack of phosphate acceptor, by the rapid increase in the concentration of adenosine triphosphate which occurs

Table 1. CONCENTRATIONS OF DIFFERENT FORMS OF PYRIDINE NUCLEOTIDES IN RAT-LIVER MITOCHONDRIA

The pyridine nucleotides were determined at zero time and after 7 min. at 30° in the presence of 40 m*M* potassium phosphate or 1·9 m*M* adenosine diphosphate. The values, expressed as µmoles/gm. protein, are the means from 13 experiments

	0 min.	7 min.
DPN	1·05	4·32
DPNH	1·6	0
DPN + DPNH	2·65	4·32
DPN $\sim I$	1·67	—
TPN	0·27	4·85
TPNH	2·1	0
TPN + TPNH	2·37	4·85
TPN $\sim I$	2·48	—

immediately after adding adenosine diphosphate. This value, 1·5 µmoles/gm. protein, is similar to our value for the diphosphopyridine nucleotide intermediate (1·67 µmoles/gm. protein).

Amytal (5-amino-5-ethylbarbituric acid), in a concentration of 1·8 m*M*, completely blocks oxidations linked with diphosphopyridine nucleotide in rat-liver mitochondria[6], acting between flavoprotein and diphosphopyridine nucleotide[7]. In the presence of 0·8 m*M* amytal, 33 m*M* nicotinamide and 1·9 m*M* adenosine diphosphate, the reduced diphosphopyridine nucleotide content of liver mitochondria decreased slowly, while the content of the oxidized form remained relatively constant. Under these conditions 75 per cent of the reduced diphosphopyridine nucleotide disappeared, presumably by conversion to the disphosphopyridine nucleotide intermediate. The diphosphopyridine nucleotide which disappeared could be recovered by dilution and addition of 2,4-dinitrophenol. A higher concentration of amytal (1·8 m*M*) completely inhibited any change in the concentrations of diphosphopyridine nucleotide or its reduced form.

Alterations in the disphosphopyridine nucleotide intermediate concentration can also be produced by the addition of substrate. The addition of β-hydroxybutyrate to liver mitochondria at 0° C., in the presence of 3·0 m*M* magnesium but in the absence of phosphate acceptor, caused the concentrations of both oxidized diphosphopyridine nucleotide and its reduced form to increase in 90 sec. The addition of α-ketoglutarate, succinate or glutamate, on the other hand, caused a sharp decrease in oxidized diphosphopyridine nucleotide without a corresponding increase in its reduced form, indicating an increase in the diphosphopyridine nucleotide intermediate. Thus this energy-rich intermediate breaks down in the presence of β-hydroxybutyrate and accumulates in the presence of α-ketoglutarate, succinate or glutamate in the absence of phosphate acceptor.

The interconversions of the various forms of diphosphopyridine nucleotide in rat-liver mitochondria may be explained by the formulation of respiratory-chain phosphorylation currently used in this laboratory[3,8]. Substituting reduced diphosphopyridine nucleotide for AH_2, flavoprotein (*fp*) for *B* in the general formulation we have:

$$(1)\quad \mathrm{DPNH} + fp + I \rightleftharpoons \mathrm{DPN} \sim I + fp\mathrm{H}_2$$

$$(2)\quad \mathrm{DPN} \sim I + X \rightleftharpoons X \sim I + \mathrm{DPN}$$

$$(3a)\quad X \sim I + \mathrm{P}_i \rightleftharpoons X \sim \mathrm{P} + I$$

$$(3b)\quad X \sim \mathrm{P} + \mathrm{ADP} \rightleftharpoons \mathrm{ATP} + X$$

$$(4)\quad X \sim I + \mathrm{H_2O} \xrightarrow{\mathrm{(DNP)}} X + I$$

(The following abbreviations are used: P_i, inorganic phosphate; ADP, adenosine diphosphate; ATP, adenosine triphosphate; DNP, 2,4-dinitrophenol; DPN, diphosphopyridine nucleotide.)

It can be seen from reactions (1) and (2) that both free *I* and *X* are needed to convert reduced diphosphopyridine nucleotide and diphosphopyridine nucleotide intermediate, respectively, to oxidized diphosphopyridine nucleotide. The addition of 2,4-dinitrophenol causes a rapid conversion of reduced diphosphopyridine nucleotide and the intermediate form to diphosphopyridine nucleotide because it produces both *I* and *X* in the hydrolytic reaction (4). The addition of adenosine diphosphate also causes a rapid appearance of oxidized diphosphopyridine nucleotide (but slower than that caused by addition of 2,4-dinitrophenol) because it produces free *X* in reaction (3*b*). It is likely that there is sufficient free phosphate in the mitochondria preparation so that reaction (3*a*) can proceed to the right. The ability of phosphate, which in reaction (3*a*) liberates *I* from $X \sim I$, to cause the appearance of diphosphopyridine nucleotide may be explained by assuming a slight uncoupling or hydrolysis of $X \sim I$ to yield free *X*.

The decrease in oxidized diphosphopyridine nucleotide and the increase in diphosphopyridine nucleotide intermediate but not in reduced diphosphopyridine nucleotide that occur on the addition of α-ketoglutarate or glutamate to liver mitochondria are explained by the reduction of diphosphopyridine nucleotide by the mitochondrial dehydrogenase followed by reaction (1). The increased amounts of both oxidized and reduced diphosphopyridine nucleotide that occur on the addition of β-hydroxybutyrate in the presence of magnesium is attributed to a reduction of diphosphopyridine nucleotide by the β-hydroxybutyric dehydrogenase followed by reaction (2). The free *X* needed for reaction (2) most likely results from a slight uncoupling by β-hydroxybutyrate.

The decrease in diphosphopyridine nucleotide with succinate is somewhat surprising since diphosphopyridine nucleotide is not a member of the succinic oxidase system. The increase in diphosphopyridine nucleotide intermediate but not reduced diphosphopyridine nucleotide may be explained by the formation of $X \sim P$ in the phosphorylation steps associated with succinate oxidation and the reversal of the high-energy-transfer steps associated with diphosphopyridine nucleotide (reactions 3*a* and 2) to form the diphosphopyridine nucleotide intermediate.

The conversion of reduced diphosphopyridine nucleotide to the energy-rich intermediate and the inhibition of diphosphopyridine nucleotide appearance by 0·8 m*M* amytal in the presence of adenosine diphosphate may be explained by the blocking of reaction (2) but not reaction (1) with low concentrations of amytal. Higher concentrations of amytal (1·8 m*M*) also block reaction (1). Thus, it is postulated that the primary site of amytal action is reaction (2).

I wish to express my thanks to Prof. E. C. Slater for his interest and helpful criticism, and to Miss Jet Moerdijk for her skilled technical assistance. This investigation was carried out during the tenure of a Life Insurance Medical Research Followship.

Further details will be published later.

GENETIC CONTROL OF THE CYTOLOGICALLY DIPLOID BEHAVIOUR OF HEXAPLOID WHEAT

By Dr. RALPH RILEY and VICTOR CHAPMAN

Plant Breeding Institute, Cambridge

COMMON wheat, *Triticum vulgare*, is a hexaploid species with 42 chromosomes in which the genomes of diploid wheat and of the diploid species *Aegilops speltoides* and *Aegilops squarrosa* are combined together[1-5]. There is considerable similarity between the chromosomes of these three diploids. Indeed, in hybrids between diploid wheat and *Aeg. squarrosa* and between diploid wheat and *Aeg. speltoides*, complete pairing at meiosis occasionally results in the formation of seven bivalents, although the mean bivalent frequency is somewhat less, being between three and four per cell[5,6]. Moreover, the attraction which results in bivalent formation in the hybrids is of such strength as to cause multivalent formation in tetraploids induced from them. However, each chromosome normally conjugates with its complete homologue at meiosis in *T. vulgare*, and only bivalents are formed. Thus, the pairing attractions between the equivalent, homoeologous, chromosomes of different genomes either no longer exists or is no longer expressed. Polyploid wheat has therefore evolved to behave cytologically as a diploid. Further, the shift has been of such efficiency that there is very little chromosome pairing even in 21-chromosome haploids of *T. vulgare*, in which intergenome pairing is not restricted by the affinity of complete homologues. The cytological distinctiveness of the equivalent chromosomes of different genomes is all the more striking in view of the close genetic relationships which have enabled Sears[7], by nullisomic-tetrasomic compensation, to recognize the seven homoeologous groups into which the complement of wheat can be arranged.

Recent results with various aneuploids have revealed something of the genetic control of the diploid behaviour of *T. vulgare*. The evidence centres on the derivatives of a 41-chromosome monosomic line, designated *HH*, which arose at Cambridge in the variety Holdfast. The formation of twenty bivalents and one univalent (Fig. 6) in *HH* monosomics is like the behaviour of all other monosomics of common wheat[8]. Meiosis is normal in the 42-chromosome segregants in the monosomic line, and in the 42-chromosome hybrids from crosses of *HH* monosomics to euploid plants of Holdfast. Therefore, the chromosomes of *HH* monosomics are structurally unaltered compared with those of Holdfast. One arm of the chromosome monosomic in the *HH* line is rather more than twice the length of the other, but the chromosome has not yet been positively identified relative to the numbering based on the variety Chinese Spring.

Monosomics of *HH* have been used in crosses with 44-chromosome plants which had the full complement of wheat chromosomes plus a single pair of rye chromosomes. From these crosses five 20-chromosome, nulli-haploid, plants have been obtained, which, by the nature of their origin, must have had the haploid complement of Holdfast minus the chromosome which is monosomic in the *HH* line. The nulli-haploids arose in (*a*) the F_1 of the cross *HH* monosomic × rye chromosome III disomic addition, and in (*b*) the F_2 of crosses of *HH* monosomic × rye II, or rye III, disomic additions[9]. All the F_1's which produced nulli-haploids in F_2 had twenty bivalents composed of wheat chromosomes and the *HH* chromosome and a rye chromosome as univalents. In each situation, therefore, the 20-chromosomes in the embryo sacs which functioned parthenogenetically must have been those which had segregated from bivalents—that is, all the wheat chromosomes except *HH*.

The meiotic pairing of the *HH* nulli-haploids has been compared with the pairing in 21-chromosome euhaploids of Holdfast. The meiotic behaviour of the euhaploid plant listed in Table 1 was similar to that of twelve other 21-chromosome plants of Holdfast examined over a period of four years. The number of bivalents in these plants never exceeded four, with a mean frequency of between 1·3 and 1·7 per cell, and trivalents were rare (Fig. 1). There was usually only one chiasma per bivalent.

By contrast, in the *HH* nulli-haploid enumerated in Table 1, which is typical of five such plants examined in two successive years, the mean bivalent frequency exceeded the maximum observed in euhaploids. Trivalents were quite frequent with as many as five in some cells (Fig. 3), although there was never more than one per cell in the euhaploids. Very many more chromosomes per cell, a mean of 11·0 compared with a mean of 2·9, were involved in chiasma-associations and a much higher frequency of closed bivalents and of 'pan-handle' trivalents resulted from more intimate pairing. As many as nineteen of the twenty chromosomes of the nulli-haploid have been observed in various associations simultaneously, although never more than nine were involved in associations in the same cell in euhaploids.

The most reasonable hypothesis to account for these observations was that the deficient chromosome carried a gene, or genes, which restricted

Table 1. Meiotic Pairing in Euhaploid and *HH* Nulli-haploid of *T. vulgare*

Type	Chromosome No.	Cells	Mean pairing			Proportion of bivalents as rings	Conjugated chromosomes per cell	
			Bivalents	Trivalents	Quadrivalents		Mean	Range
Euhaploid	21	100	1·38 ± 0·09	0·07	—	0·00	2·86 ± 0·23	0–9
Nulli-haploid	20	75	4·16 ± 0·12	0·86 ± 0·03	0·02	0·23	10·95 ± 0·33	4–19

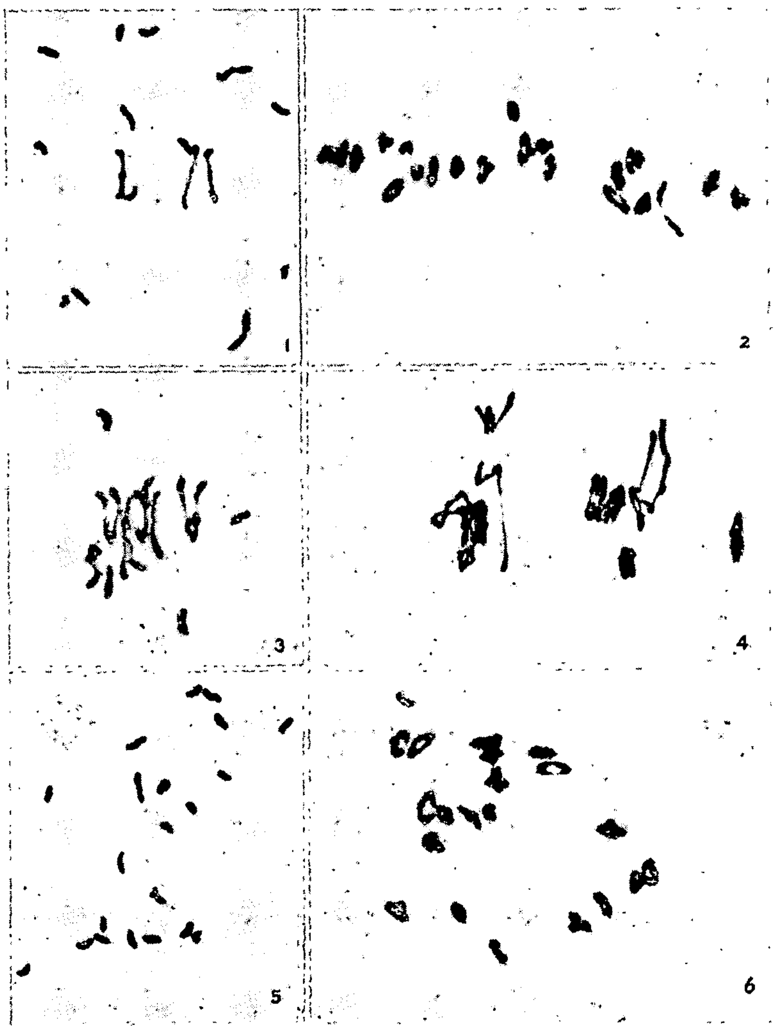
intergenomic, homoeologous, pairing ; the alternative being that association between randomly distributed duplicate segments was normally inhibited. On either view, there being no other independent mechanism, in the absence of the pairing restriction normally undetected affinities were expressed. Crucial evidence that the pairing was homoeologous rather than random was afforded by the high frequency of trivalents and the infrequency of quadrivalents.

If homoeologous pairing could take place in *HH* nulli-haploids, it was argued that 40-chromosome nullisomics deficient for the *HH* pair should deviate from the strictly bivalent-forming regime of *T. vulgare*. Consequently, three *HH* nullisomics have been examined. All had large and frequent multivalents, and associated univalents, at meiosis. No method has yet been found of consistently preparing well-spread pollen mother cells of this material, but the complexity of the behaviour is readily apparent (Fig. 4). More than half the cells have at least one multivalent, usually a quadrivalent, and many have several. Associations of three, four, five and six are common, but no higher multivalents have been observed. However, the greater the number and size of multivalents the less is the chance of disentangling the snarl, so there is danger of observational bias. No doubt, also, there are homoeologous, or allosyndetic, bivalents which would be undetected unless markedly heteromorphic. The magnitude of the meiotic disturbance is therefore hard to assess ; nevertheless, it is clear that, in the absence of the *HH* chromosome, *T. vulgare* ceases to be a stable bivalent former, a classical example of the autosyndetic pairing allohexaploid, and behaves as an intermediate, auto-allopolyploid.

The diploidizing mechanism is effective in the hemizygous state in monosomics and in euhaploids. Furthermore, in a haploid plant which had twenty normal wheat chromosomes plus the iso-chromosome formed from the long arm of the *HH* chromosome (Fig. 5), meiotic pairing was the same as in euhaploids. Moreover, there was no multivalent formation in a 41-chromosome monosomic which had twenty normal pairs of Holdfast chromosomes and in which the *HH* chromosome was represented only by a single telocentric of the long arm. The long arm alone is thus effective in prohibiting homoeologous association ; but no evidence is available on the effects of the short arm alone. It may be that both arms have genes with equally effective control over the pairing behaviour, but this seems unlikely. The control of bivalent formation is probably restricted to one arm, and may indeed be effected by quite a localized region.

The implications of these results are both theoretical and practical. First, there has been considerable discussion on the methods by which many polyploids have attained their cytologically diploid character, with its obvious advantages in fertility and genetic stability. Several authors have favoured the theory that this situation has been achieved by the selective accumulation of many small changes of chromosome structure, which lead to the divergence of homoeologues. However, the selection of the localized product of a single mutational step, such as seems likely to have happened in wheat, is very much simpler to envisage, and would clearly be a more rapid and efficient process. To compare the frequencies of the genetical, or cytological, determination of diploid meiotic behaviour, other allopolyploid species should be examined for evidence of a mechanism similar to that in wheat.

Secondly, knowledge of the pairing restricting mechanism may be useful in wheat improvement.



First metaphase of meiosis in Feulgen- and orcein-stained squashes of pollen mother cells of various derivatives of *T. vulgare*

(1) 21-Chromosome euhaploid with 4 bivalents (one widely stretched) and 13 univalents. (2) Euploid with 21 bivalents. (3) 20-Chromosome *HH* nulli-haploid with one 'pan-handle' and 4 chain trivalents, one bivalent and 3 univalents. (4) 40-Chromosome *HH* nullisomic with one ring of six, 2 chains of four and 13 bivalents. (5) 21-Chromosome haploid in which the *HH* chromosome is an isochromosome of the long arm ; one stretched bivalent, 18 normal univalents and the isochromosome paired interbrachially with two chiasmata. (6) 41-Chromosome *HH* monosomic with 20 bivalents and one univalent. (× 770)

ICSU REVIEW

Published quarterly for the

INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

Editor :
SIR HAROLD SPENCER JONES
Formerly Astronomer Royal (London)
Editorial Advisory Committee :
W. W. ATWOOD (Washington, D.C.), M. FLORKIN (Liège), P. HUBER (Basel)

The ICSU REVIEW will be a quarterly publication concerned with the philosophy of international relationships in science, and with the advancement of scientific knowledge through the stimulation and co-ordination of international co-operation. In addition to special articles, it will contain information about the activities of the ICSU and of the scientific unions, reports of some of the symposia organized by the unions which are normally concerned with growing points in science, reviews of publications of the unions and of special committees of the ICSU, as well as factual information about forthcoming meetings arranged by the ICSU and the unions. It will serve to bring the ICSU, the national organizations that adhere to ICSU, and the international scientific unions into closer relationship and provide a forum for the discussion of problems of mutual interest.

subscription price : £1.10.– $4.50 Dfl. 16.–

JOURNAL OF THE LESS-COMMON METALS

An International Journal on Their Chemistry and Metallurgy

Editors :
PROFESSOR J. W. CUTHBERTSON, D.Sc., F.I.M., A.M.I.E.E. (Metallurgy),
Department of Metallurgy, The University, University Park,
Nottingham, England.
DR. F. FAIRBROTHER (Chemistry), The University of Manchester,
Department of Chemistry, Manchester 13, England.

PROFESSOR L. M. PIDGEON (Toronto)
DR. A. R. POWELL (Wembley)
MR. OLIVER C. RALSTON (Hyattsville, Md.)
PROFESSOR HILL W. WORNER (Melbourne)
DR. L. F. YNTEMA (Menlo Park, Calif.)

The less-common metals, such as titanium, niobium, beryllium, uranium, and numerous others, are rapidly growing in importance. Some of these metals were formerly of little more than academic interest, but many of them have unique properties and the recent rapid advances in metallurgical science and in technology have created an increasing demand for such metals and their compounds. This demand is likely to expand rather than diminish.

The new Journal will cover the chemistry and metallurgy of these metals, and will provide ready access to information on their extraction, preparation, chemical and physical properties, and fields of application. It will also deal with the metallography, properties, and uses of their alloys.

The prime object of the new Journal will be the dissemination of knowledge on these metals, their compounds and their alloys. It will be an outlet for the publication of the latest research on all aspects of their properties and uses, and should thus stimulate their further study and practical advancement. The availability of so much information in one place should prove an attraction to all scientists and technologists who are interested, even if only remotely, in this expanding field of metallurgy.

subscription price : £5.7.6 $ 15.00 Dfl. 57.–

Solid State Physical Electronics

PROFESSOR ALBERT VAN DER ZIEL

A comprehensive introduction to the physics of the solid state devices that are used, or are being developed for use, in the electronics industry. *Illustrated* 37*s* 6*d*

General Microbiology

ROGER Y. STANIER, MICHAEL DOUDOROFF and EDWARD A. ADELBERG

This book attempts to present a modern synthesis of microbiological knowledge for university students of the biological sciences. Students new to this subject will find it particularly useful. *With photographs and diagrams* 50*s*

Looking at Chromosomes

JOHN MCLEISH and BRIAN SNOAD

The aim of this book is to demonstrate, by means of a continuous series of photographs and illustrations, how cells and the hereditary substances they contain behave during the growth of a living organism, how the cells which function in reproduction come to be formed and, finally, how the hereditary substances are passed on from parents to offspring. Of great value to students with some knowledge of biology.

48 *plates and many diagrams* 16*s*

An Atlas of Airborne Pollen Grains

H. A. HYDE and K. F. ADAMS

This atlas is intended primarily as an aid to the identification of pollen grains in the fresh condition. The ninety-two species described are those which can be observed at a magnification of about 1,000 diameters. The book should be of value in studies of airborne pollen in general and in relation to hayfever, and, to a lesser degree, the pollen loads of bees, and pollen in honey and in peat. *Illustrated* 36*s*

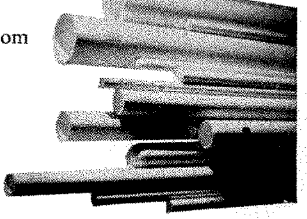
RECRYSTALLISED ALUMINA

$99.7\%\ Al_2O_3$

This is Morgan Refractories recrystallised alumina; the purest available anywhere in the world. It is hard, extremely resistant to abrasion and mechanically strong; tubes, crucibles, trays can be made very thin, and therefore relatively immune to thermal shock.
Recommended maximum service temperature—1950°C.
Thermal conductivity at 1000°C 40 BThU sq. ft./hour.

Standard tubes are available from stock up to 65 mm. bore, but we make very much larger tubes—up to 165 mm. bore, which are the largest made anywhere in this material.



Send for catalogue Ref. RD79.

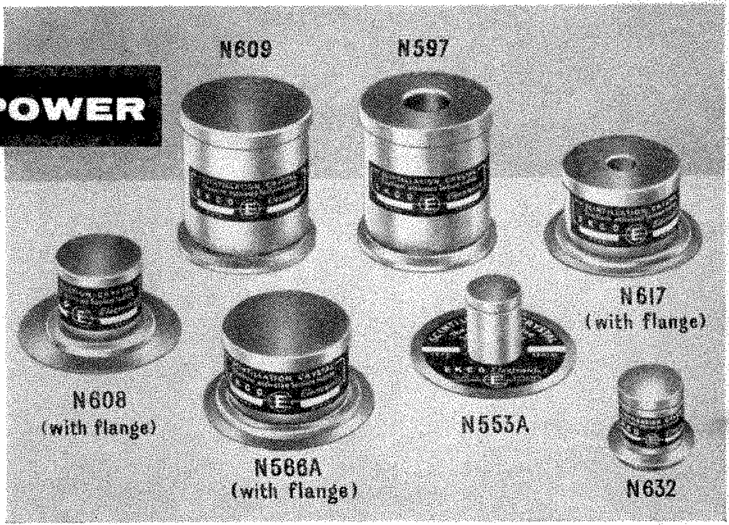
HIGH STOPPING POWER

Ekco Thallium-activated Sodium Iodide crystals have high stopping-power, many times the light output of plastic phosphors and a spectral response which at 4,100 Angstroms closely matches photo-multiplier tube response. They may be fitted with flanges for convenient mounting and are available in a range of types to cater for various gamma-ray counting and spectrometry applications.



CRYSTAL DIAMETERS AND DEPTHS:
N609 1¾" x 2", **N597** 1¾" x 2" (well ¾" x 1½"), **N617** 1½" x 1" (well ½" x ⅜"),
N608 1" x 1", **N566A** 1½" x 1", **N553A** 11/16" x 1", **N632** 13/16" x 1".

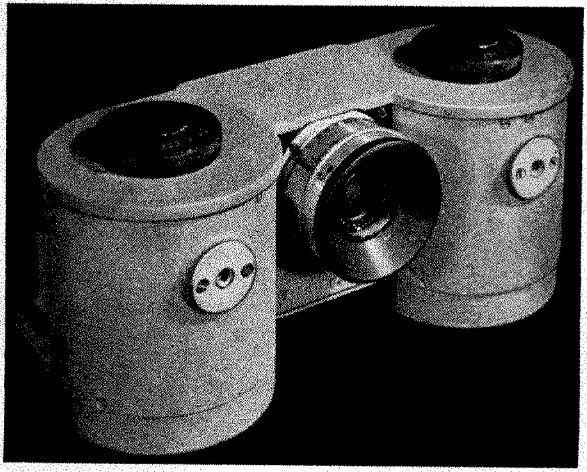
photographic

recording



The Shackman Autocamera is a recording instrument designed to cover a wide field in industrial and scientific work where the automatic production of micro-films is required. It is a precision instrument suitable for all purposes where long periods of visual observation and manual recording are impracticable, such as Oscilloscope Recording, Process Timing, Photomicrography and Instrument Recording. It can be fully automatic in its operation, requiring only a short single electrical impulse to operate the shutter and transport the film. A full range of accessories is available including control units and intervalometers. The Autocamera is adaptable also for industrial photography, stereoscopy, document copying and many other special applications.

The utilization of related diploid species, for example, in the genus *Aegilops*, in wheat breeding is hampered because the chromosomes of the diploids do not pair with those of wheat, in intergeneric hybrids. To overcome this obstacle, Sears[10] was forced to use X-rays to induce the translocation of a disease-resistance gene of *Aeg. umbellulata* on to a wheat chromosome, and others[9, 11,12] have been compelled to explore alien chromosome addition and substitution lines. However, this intergeneric allosyndetic pairing may well take place in the absence of the *HH* chromosome, just as it does between chromosomes of the different genomes; alien genes could then be introduced into wheat chromosomes by normal recombination. Critical hybrids of this constitution can be extracted from crosses of *HH* monosomics by the appropriate diploid.

Finally, nullisomic plants of this constitution may be used either within single varieties or in intervarietal hybrids in 'intergenome exchange' breeding. Thus a useful gene which showed a dose effect could be obtained duplicated or triplicated, represented on each chromosome of the homoeologous group. The chromosome structure within a variety could be re-patterned by breeding from *HH* nullisomics. Further, if an *HH* nullisomic were also an intervarietal hybrid, the release of variation, and the range of segregation in later generations, would be very much greater than from a euploid hybrid. Thus, the *HH* nullisomic may afford access to otherwise unavailable genetic variation.

However, the exploitation of *HH* nullisomics depends upon their fertility. There is no natural self-fertility, but a reasonable seed set has been obtained by pollinating *HH* nullisomics with Holdfast euploids, although the reciprocal cross has been unsuccessful. There were several large multivalents at meiosis in the one 41-chromosome derivative, so far examined, of an *HH* nullisomic pollinated by a euploid. The *HH* chromosome regained from the euploid pollen was always a univalent, and homoeologous pairing must have been prohibited by its presence. The multivalents were thus indicative of translocation heterozygosity, the outcome of homoeologous pairing in the nullisomic parent. Homozygotes for new structural conditions can be derived from such plants, although further back-crossing may first be necessary to reduce the extent of structural alteration.

Knowledge of the situation described already begins to make plain some of the problems of wheat cytogenetics and perhaps of polyploidy in general. Further investigation cannot fail to extend this advantage and may well contribute to the cytogenetic manipulation of wheat for practical breeding purposes.

The interest of Dr. G. D. H. Bell in the development of this work is gratefully acknowledged.

SUCROSE CRYSTAL INCLUSIONS

By H. E. C. POWERS

Tate and Lyle, Ltd., Thames Refinery, London, E.16

TWO years ago I reported[1] the presence of water inside the sucrose crystal as a normal phenomenon, the percentage varying between wide limits. Measurements of vapour pressure, taken before and after crushing, demonstrated this qualitatively, but at that time no adequate quantitative analytical procedure was available for precise measurement. Two new methods have since been developed in our research laboratories[2]. The evidence obtained so far indicates that with refined sucrose crystals of the normal size of granulated sugar, the internal water ranges at least from 0·01 to 0·04 per cent, while with large crystals approaching an inch in length, the range of internal water may be ten times greater (0·1 to 0·4 per cent).

Since this included water is due to the 'growing in' of mother syrup by the layers during the growth of the crystal[1], the composition of this internal syrup will be essentially that of the mother syrup.

Given the composition of the mother syrup, together with the amount calculated from the included water, it is possible to estimate the amounts of the various non-sucrose constituents held in syrup inclusions.

Results obtained so far suggest that water-soluble organic colouring matter is held entirely in these syrup inclusions, but that certain ionized salts are frequently found in far higher proportion than that calculated on the basis of included syrup. Calcium and potassium salts seem to be thus held, and in particular, the potassium salt of imidodisulphonic acid[3], and calcium magnesium aconitate in beet and cane sugars respectively. It is not known whether these are deposited as crystals which are then built-in by the layer growth, or whether they are held by some ionic or molecular similarity of structure with some part of the sucrose molecule.

Non-crystalline insoluble matter may also be 'grown in' by the layer growth, as, for example, starch, which is found in the sap of certain strains of sugar cane. This appears to be attracted towards the growing crystal face, since after several successive crystallizations, the starch is found in the crystals in a higher ratio to soluble salts than in the original juice. Certain colloids appear to act similarly.

Further study of sucrose crystals under the microscope has also revealed gaseous inclusions. By watching chosen specimens in the act of dissolving under the microscope, when an inclusion of syrup is breached, the heavy syrup may be seen streaming downwards, whereas when a gaseous inclusion is breached a bubble may be seen to strain like a balloon, then to break away and rise rapidly to the surface. The probable origin is that air dissolved in the original crystallizing syrup became supersaturated and formed as bubbles on the growing face. These were then overgrown by the layers. One obvious effect of these inclusions is to explain the widely varying figures given in the literature for the specific gravity and melting point of sucrose—1·58–1·60 gm./cm.^{3} and 160–186° C., respectively. By selecting two crystals under the microscope with maximum and minimum visible inclusion and determining their specific gravities, we have obtained figures of 1·582 and 1·594 gm./cm.^{3} respectively.

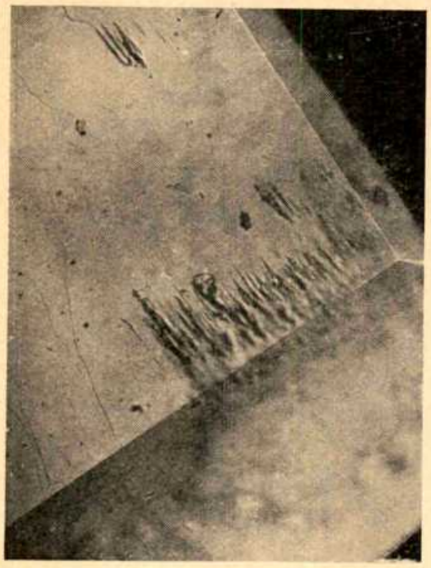

Fig. 1. Fjord-type inclusions (note also layer growth)

These fluid inclusions take several distinctly different physical forms (see Figs. 1–5).

(1) A fjord-like form, the position of which in the crystal appears to be completely random, though frequently several are present roughly parallel to one another.

(2) A rather symmetric form, of which the most perfect and complete is usually referred to as the 'hour-glass' shape, since when viewed toward the 100 face, the familiar hour-glass shape is apparent. Sometimes only a section of this may be present.

(3) Orderly patterns indicating some symmetry—sometimes, but certainly not always, the result of *Einwurf* boiling (using crystals from one boiling as seed for a second).

(4) Veil-like systems, in appearance suggesting a wisp of gossamer flicked through the crystal, with no respect for the axis.

(5) Local clouds or drifts of approximately spherical droplets in diameter from 100μ down at least to 1μ.

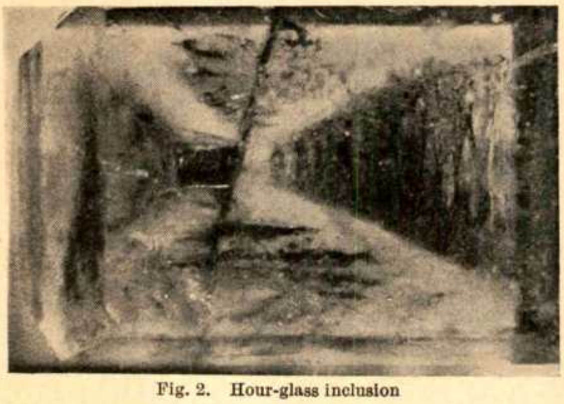

Fig. 2. Hour-glass inclusion

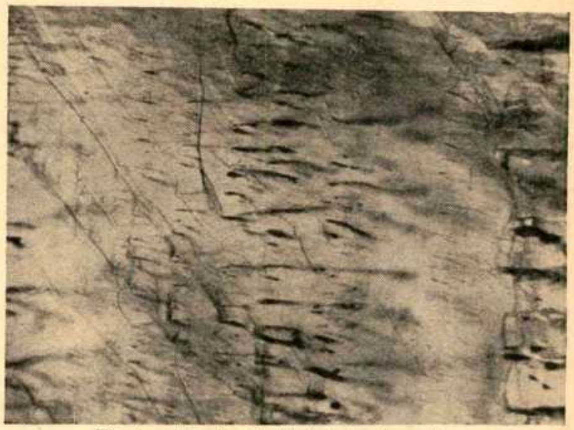

Fig. 4. Complex rhythmic inclusion pattern

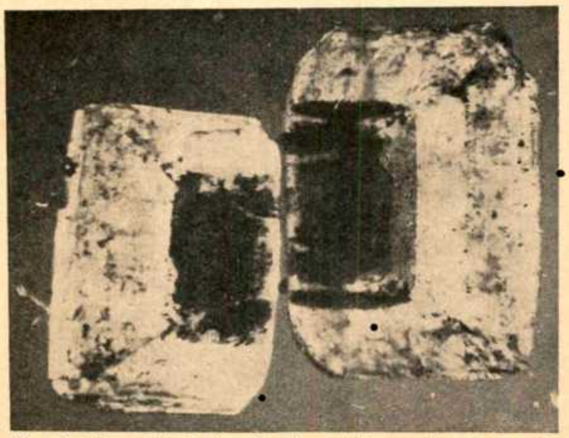

Fig. 3. *Einwurf* inclusion, showing evidence of lower growth-rate in one direction

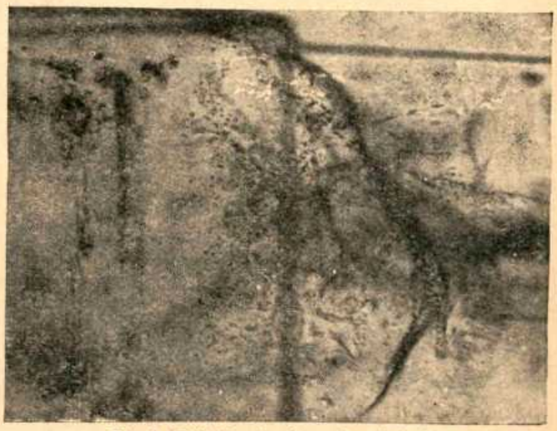

Fig. 5. Veil, showing hour-glass inclusions

The evidence suggests that the first three are the result of layer growth 'building-in' liquor or air locally, and a fortunate micro-film shows the fourth to be the result of a sudden crack, due to growth or temperature strain. Whereas the initial veil consists of a continuous film layer, this appears to be unstable, and I am fairly confident that, if conditions of temperature and time permit, the film slowly 'congeals' to a more stable condition. The first stage reminds one of a network of isthmuses; the later stage is the network of detached droplets. This I have classed as the distinct type 5, since it is possible that some of these droplets may have been 'grown in', as with type 1.

It is interesting that layer growth is able to proceed around such dissimilar foreign intrusions as thread, wire, sheets of metal, local spots of liquor at lower supersaturation and even bubbles of air, and that without apparent disturbance to the crystal symmetry. Dr. A. F. Seager originally directed my attention to the fact that the major inclusions are normally to be found in that portion of the crystal which has grown most rapidly, in conformity with the usual belief that rapid growth increases the tendency to form inclusions. I have now found many instances of this phenomenon.

Another lucky micro-film suggests that one part of one face of a crystal may exhibit a local 'spurt' in the rate of growth. This may play a part in the formation of the larger inclusions. Artificial inclusions have been made successfully by boring a hole through a large crystal, then immersing it in a supersaturated solution, when the two exits may be sealed, thus closing the liquor-filled tunnel.

The evidence, both with mosaic and with the many types of inclusion, indicates that the interior of sucrose crystals normally exhibits great local variation in structure.

So much crystallographic research is in the nature of a post-mortem upon geological crystals formed in the distant past. It would appear that the study of such a crystal as sucrose in active growth should provide the key to several features common to many crystalline materials.

USE OF TWO PROPERTIES OF THE VIRUS OF FOOT-AND-MOUTH DISEASE IN STUDIES OF ITS MULTIPLICATION

By SHEILA F. CARTWRIGHT and H. V. THORNE

Research Institute (Animal Virus Diseases), Pirbright, Surrey

In a previous study of the multiplication of the virus of foot-and-mouth disease in cultures of tongue epithelial cells[1], it was found that infective virus remained bound to the cells during the latent period, that is, up to 2–2½ hr. after infection even after treatment of the cells with specific antiserum. The number of infective units of virus (*ID*50/ml.) was approximately equal to the number of cells producing virus; it was therefore not possible to decide whether this infectivity was due to virus other than that producing infection, adsorbed in such a way that it resisted the action of antiserum, or to virus which after entering and infecting the cell remained infective. Since in studies of phage and other viruses[2–6] the infecting virus has been shown to become non-infective after penetration, it was important to decide between these possibilities.

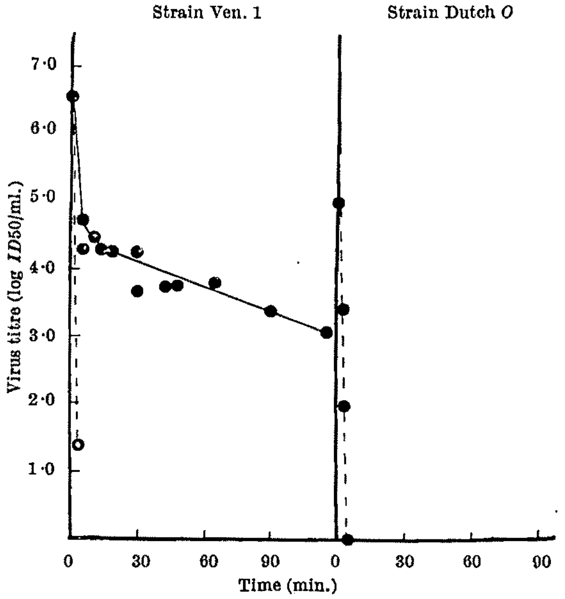

Fig. 1. The *p*H-inactivation of the Ven. 1 and Dutch *O* strains of the virus of foot-and-mouth disease; ●—●, *p*H 6·0; ○—○, *p*H 5·7

Two properties of the virus of foot-and-mouth disease have been utilized for this purpose. In a paper by Cartwright and Thorne[7], the resistance of the virus to sodium dodecyl sulphate and other detergents is described, with its application to the lysis of tongue epithelium and pig kidney cells and extraction of virus throughout the growth-cycle. Sodium dodecyl sulphate has advantages in this type of work over other methods of disrupting cells in the rapidity and completeness of its action. With this reagent and again using antiserum to inactivate extracellular virus, infectivity of the same order was still found during the latent period with both cell types.

Secondly, the well-known instability of this virus at *p*H values below neutrality[8–10] suggested lowering the *p*H of the culture as an alternative means to the use of antiserum or washing. The possible advantages of *p*H change are the rapidity and completeness of the inactivation, and the ease of penetration of the hydrogen ion into the cell surface. The results of using *p*H inactivation in conjunction with the sodium dodecyl sulphate method of disruption to determine virus remaining associated with the cells are reported here.

The characteristics of the inactivation of the two strains of virus used, Ven. 1 and Dutch *O* (1957), at relevant *p*H values are shown in Fig. 1. At *p*H 6·0 the Ven. 1 strain is inactivated at a slower rate than Dutch *O* and in addition a small fraction of the virus population (~ 1 per cent) is inactivated at a much slower rate than the main fraction. A similar fraction was found in the strain studied by Bachrach *et al.*[10]. At *p*H 5·7, however, the rate of inactivation is such that 99·9 per cent of both Ven. 1 and Dutch *O* virus is inactivated in less than 1 min.

In the experiments with cell suspensions the following procedure was used. Suspensions of tongue epithelial and pig kidney cells were exposed to seed virus (1–100 *ID*50/cell) for 30 min. at 37° C., when the suspension was adjusted from the normal *p*H (7·6) to *p*H values in the range 5·0–6·0 either by sedimenting the cells and resuspending in 0·02 *M* acetate-buffered medium (Tyrode's + 0·5 per cent lactalbumin hydrolysate) or rapidly by the addition of 0·1–1·0 *M* acetic acid. After 5–70 min. the *p*H was restored to 7·6 either by sedimenting the cells and resuspending in normal medium or by the addition of 0·01 *N* sodium hydroxide or *p*H 7·6, 0·04 *M* phosphate buffer. A portion was then titrated by inoculation of unweaned mice[11] to determine the number of infected cells, and a portion, treated with an equal volume of 1·0 per cent sodium dodecyl sulphate in phosphate buffer to destroy the cells, was titrated to determine residual infective virus. The remainder was incubated at 37° C. and titrated to determine the yield of virus after multiplication.

From the representative results in Table 1, the virus associated with the cells after infection with the Ven. 1 strain of virus is now seen to be of the order of 1 infective unit/100 infected cells, while the virus produced remains normal, within the limits of error of titration (± 0·3 log unit), for *p*H treatments at 5·5 and above up to 15 min. Below *p*H 5·5 most of the cells become non-viable in the medium used. Longer times at low *p*H appear to slow down the multiplication of virus, although the eventual yield is normal; this is now being investigated.

Table 1. Latent Period Infectivity. Strain Ven. 1 in Tongue Epithelial Cells

*p*H	Log No. cells/ml.	Infected cell titre Log No./ml.	Per cent ratio cell-associated virus / Infected cell titre	Yield *ID*50/ml.
6·0	6·3	5·1	0·5	7·6
5·9	6·6	5·0	1·0	—
5·7	6·7	4·9	1·0	7·6
5·5	6·8	5·3	0·1	7·8

When the virus is kept in contact with the cells for times less than 30 min. before rapid adjustment to low *p*H (5·7), the cell-associated virus at short adsorption times is reduced still further (Fig. 2), to about 1 infective unit/10^4 infected cells, although the number of infected cells is the same within the experimental error after 1 min. as after 30 min. adsorption. There is a steady increase in the cell-associated virus with time of adsorption until the normal level after 30 min. adsorption is reached. No increase in the cell-associated virus with time was observed with the Dutch *O* strain of virus. It is possible that the greater cell-associated infectivity with the Ven. 1 strain is related to the heterogeneity of this strain towards *p*H inactivation.

These experiments show that the virus of foot-and-mouth disease becomes non-infective on entering the cell. A rough estimate of the rate at which virus enters the cell and becomes non-infective can also be made. The number of infected cells after an adsorption time of 1 min., followed by lowering the *p*H, was shown to be of the same order as after a 30 min. adsorption period. Determination of the Dutch *O* strain virus surviving after increasing times at *p*H 5·7 showed that the extracellular and adsorbed virus was reduced from a total of about $10^{7·7}$ *ID*50/ml. to $10^{2·5}$ *ID*50/ml. (1 *ID*50/100 infected cells) in less than 30 sec. In addition, the action of sodium dodecyl sulphate is so rapid that no appreciable penetration could occur after *p*H treatment. It can therefore be concluded that adsorption and penetration must occur in less than 1 min. at 37° C.

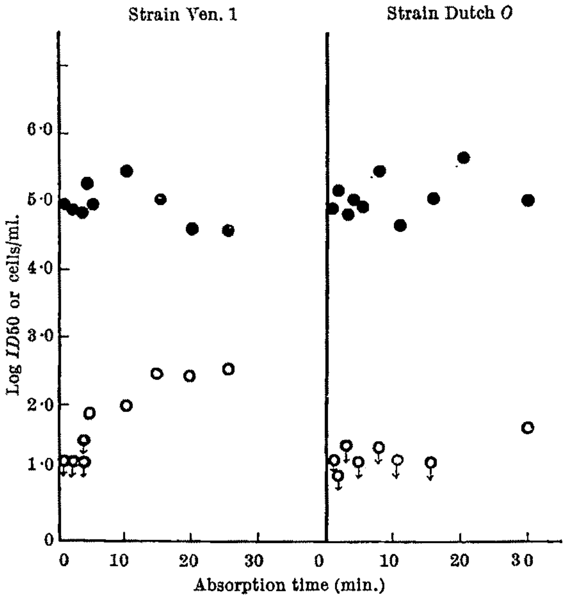

Fig. 2. The number of infected tongue epithelial cells and titre of cell-associated virus resulting from adsorption of the Ven. 1 and Dutch *O* strains of the virus of foot-and-mouth disease at 37° C. (seed virus $10^{7·8}$ *ID*50/ml.; cells $10^{6·6}$ ml.; ↓ represents titre ≮ that indicated). ●, Infected cells; ○, cell-associated virus

The apparently high level of adsorbed virus resistant to antiserum[1] may be related to the small proportion of cells which become infected in this system, since when this virus is expressed as a proportion of the total number of cells it is comparable with the levels of cell-associated virus in systems, such as that of the virus of Newcastle disease in chick embryo lung epithelial cells in which all cells are infected[12].

The results reported here indicate that by making use of the instability of the virus of foot-and-mouth disease at low *p*H in conjunction with its resistance to sodium dodecyl sulphate, further information on the adsorption and penetration of virus and on the succeeding stages of virus multiplication should be obtained.

Carcinogenic Activity and O-Alkylation

It is well known that many natural products, flower pigments, essential oils, alkaloids, etc., contain methoxy-groups, and that some of these compounds show remarkable biological activities, for example, colchicine, mescaline, etc. Despite the enormous amount of work done on the correlation of biological activity with the chemical structure, surprisingly little attention has been devoted to the biological effects connected with O-methylation of phenolic groups (compare, for example, Sexton[1]). Yet examples of its influence have been known for a long time (for example, morphine and codeine). The situation is likely to change in view of the recent discovery that O-methylation can occur in the animal body[2]; the reverse process, O-demethylation was observed in mammals about twenty years ago[3]. In view of the finding that the methyl group of methionine is also involved in O-methylation[4] the knowledge acquired from the study of N-methylation will no doubt help in the understanding of the interrelation of these two types of reactions.

With reference to carcinogenic activity, I was first impressed by the decisive part which O-methylation can play when the methylation product of the almost inactive phenolic metabolite of 3 : 4-benzopyrene produced tumours in mice[5]. Pure 8-methoxy-3 : 4-benzopyrene was then synthesized[6] and proved to be one of the most effective carcinogens for the skin and for the subcutaneous tissues of both mice and rats, surpassing in this respect the parent hydrocarbon[7]. Carcinogenic activity, though of a lesser degree, is exhibited by several other isomeric methoxy-3 : 4-benzopyrenes and also by methoxy-derivatives of other polycyclic hydrocarbons[8] (Table 1). The methoxy-groups, as well as the methyl-groups, often increase the efficacy of the hydrocarbon, but the effect depends to a striking degree on the number of the methoxy-groups and on the positions of substitution. The paucity of available data do not yet permit generalizations to be confidently made. Thus, methyl ethers at metabolically oxidized positions are not necessarily the most active: 4′-methoxy-1 : 2-benzanthracene was inactive, while the 3-, 5- and 10-isomers produced tumours.

Restoration or increase of carcinogenic activity by O-methylation is not confined to polycyclic aromatic hydrocarbons, but appears to be more generally encountered[9] (Table 1). Some examples have been reported recently among compounds representing 'remote' carcinogens, which usually induce tumours not at the site of application but in internal organs, such as liver, bladder, etc. It is not unlikely that the actual carcinogens are formed when these compounds are metabolized in the body. Indeed, in the case of some aromatic amines, the metabolic oxidation products, *o*-hydroxamines, proved to be 'local' carcinogens, when implanted in the mouse bladder. Only very few of their methyl ethers have so far been tested, and these appear to be more active than the hydroxy-compounds. The fact that 1-methoxy-2-aminonaphthalene, 3-methoxy-4-aminodiphenyl and 3-methoxy-4-aminostilbene have been reported carcinogenic[9] is of significance. It would be of interest to know whether all these compounds show 'local' carcinogenic activity when applied to tissues other than the bladder.

It is of particular interest that recently some *o*-hydroxamines which are normal intermediary body metabolites, such as 3-hydroxykynurenine, 3-hydroxyanthranilic acid, and 2-amino-3-hydroxy-acetophenone have been reported to produce tumours

Table 1. Comparison of Carcinogenic Activity of some Hydroxy- and Methoxy-Derivatives of Carcinogens

Compound	Carcinogenic activity	Hydroxy-derivatives Position of substitution	 Carcinogenic activity	Methoxy-derivatives Position of substitution	 Carcinogenic activity
1 : 2-Benzanthracene 	±	4′ 3 8 10	– ± – –	4′ 3 5 10 3 : 10-di 9 : 10-di	– ++ ++ +++ – –
1 : 2–5 : 6-Dibenzanthracene 	+++	9 – 3′ : 7′-di 4′ : 8′-di 2′ : 6′-di	– – – –	9 3 9 : 10-di	++ – –
3 : 4-Benzopyrene 	+++	4′ 2 5 6 8	– – – + ±	4′ 5 6 (or 7) 8 5 : 8-di 5 : 10-di	– ++ ++ ++++ – –
4-Dimethylaminoazobenzene 	+++	2′ 3′ 4′ 2 3	– – – – –	2′ 3′ 4′	++ +++ ++

when tested by the bladder implantation method. The 8-methyl ether of xanthurenic acid was again more effective than the latter, 4 : 8-dihydroxyquinoline-2-carboxylic acid[9].

More data are urgently needed on the biological activities of methyl ethers of phenolic compounds normally present in tissues, and on the conditions which may affect the equilibrium between metabolic O-methylation and O-demethylation—evidently of paramount importance for carcinogenic activity.

The evidence already available is sufficient to warrant further exploration for carcinogenic activity also of other alkyl ethers of such phenolic compounds. In this connexion the finding of carcinogenic activity among some alkylating agents is of interest. These alkylating agents have been studied in connexion with the cross-linkage hypothesis of carcinogenesis[10]. Their role as agents which could alkylate phenolic compounds deserves to be considered.

I wish to thank Dr. J. W. Cook and Dr. J. M. Barnes for very valuable discussions.

Carnosine Phosphate as Phosphate Donor in Muscular Contraction

UNDER the above title Goodall[1] showed that a mixture of carnosine di- and mono-phosphates has a relaxing action practically identical with that of creatine phosphate on the glycerol-extracted muscle fibre. He raised the question of the presence and role of this substance in muscle, and pointed out that its non-detection so far may be because it is so much more acid-labile than creatine phosphate[1,2].

In order to provide the energy for the 125 gm. cm. of external work done per gram of muscle in a typical twitch a 'high-energy' phosphate compound would have to be present at a concentration of at least 0·25 µmole per gm. muscle. (This calculation takes a low value for the external work done, neglects the heat produced in the muscle, assumes 100 per cent efficiency in energy transduction and a high value (12,000 cal.) for the energy delivered per mole of compound broken down.) A more probable figure would be 0·5 or more µmole per gm. muscle[3,4]. Since preliminary experiments showed that large amounts of carnosine phosphates were not present in muscle the following procedure was employed. The very slow, thin, paired, striated, retractor penis muscles of turtles were used. This muscle can be frozen in the relaxed state without change in length, and measurements of the longitudinal electrical conductivity with thermally insulated electrodes showed that the centre of the muscle was frozen in less than one-fifth of the time needed for a normal contraction at 0° C. This means that there was no time for a possible isometric contraction of the internal parts of the muscle to occur during freezing, which might have vitiated the results. The muscles were immersed at 25° C. for a total of 4 hr. in a physiological salt solution containing radioactive inorganic orthophosphate. After 2 hr. they were stimulated electrically several times and allowed to recover. This procedure causes a chemical turnover of all phosphate compounds involved in muscle contraction and ensures a close approach to equality in the specific radioactivities of the labile phosphate compounds in this tissue[5]. Thus if carnosine phosphates were present in even as low a concentration as 0·25 µmole per gm. muscle the total radioactive counts per minute in this compound would have to be at least 0·25/13, that is to say, 0·019 times the total radioactivity in the creatine phosphate which is present at a concentration of 13 µmoles per gm. muscle.

At the end of the incubation period the muscles were attached to isotonic levers, cooled to 0° C., frozen in the relaxed state in melting dichlorodifluoromethane (– 155° C.), and powdered at – 198° C. Carrier quantities of a mixture of non-radioactive synthetic carnosine di- and mono-phosphates[2] were added to preserve any such radioactive material in the tissue from possible losses during isolation. The powder was extracted at 0° C. in 20 per cent v/v

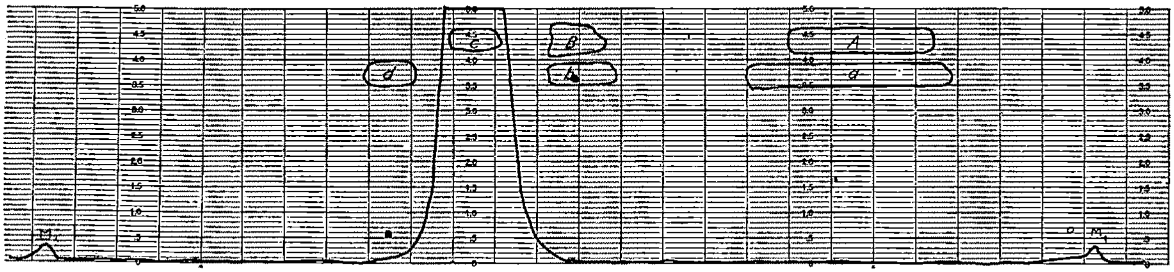

Fig. 1. Distribution of radioactivity in muscle extract treated with barium. *A*, *B* and *C* correspond to the positions on the chromatogram of carnosine diphosphate, carnosine monophosphate and creatine phosphate respectively as shown by an acid-molybdate spray for phosphorus. *a*, *b* and *d* correspond to carnosine diphosphate, carnosine monophosphate and tissue carnosine as shown by a spray of *p*-nitrobenzenediazonium fluoborate after treatment with acid *in situ*. M_1 and M_2 are radioactive marker spots; *O* is the origin. Full-scale deflexion of the scanner at the sensitivity used for this graph was 3,000 c.p.m. The R_F of the creatine phosphate is 0·56

ethanol/water and the radioactive inorganic phosphate and nucleotides removed from the extract by repeated isotope dilution and precipitation with barium at pH 8·2. The solution was then chromatographed on paper with a mixture of 65 volumes of 95 per cent v/v ethanol/water and 35 volumes of 0·1 M potassium carbonate. Examination of the paper with an automatic radioactivity scanner and with sprays for phosphate and imidazole compounds gave the results shown in Fig. 1. Although the added carnosine phosphates had survived the isolation procedure there was a complete absence of associated radioactivity. The creatine phosphate contained 18,000 c.p.m., so the carnosine phosphates should have had at least 18,000 × 0·019 = 340 c.p.m. However, the radioactivity attributable to the carnosine phosphates was less than 30 c.p.m. A similar absence of carnosine phosphates was found in these muscles contracted at 0° C. under conditions where it had previously been found that net changes in adenosine tri-, di- or mono-phosphates and in creatine and creatine phosphate were either unobservable during a contraction or too small to account for the work done[3,4,6].

These results appear to exclude the possibility that the carnosine phosphates in the Severin, Georgievskaya and Ivanov preparation[2] are phosphate donors in muscle contraction and show that, if present at all, their concentration in muscle must be less than 0·02 µmole per gm.

Deoxycytidine in Urine as an Indicator of Changes after Irradiation

IONIZING radiation causes obvious changes in the metabolism of deoxyribonucleic acids[1]. An experiment was therefore carried out to determine whether exposure of rats to ionizing radiation causes excretion of catabolites or intermediary products of deoxyribonucleic acids in urine.

Adult white male rats (Wistar strain) weighing 200–320 gm., kept under standard conditions, were used. The animals were irradiated with 76 r./min. at a distance of 40 cm. at 200 kV., 15 m.amp. with a filter consisting of 0·5 mm. of copper and 1 mm. of aluminium. Urine was collected from unrestrained rats kept in glass metabolic cages, making possible the separate collection of urine and stools, and from animals partly restrained in metabolic cages.

Dische's reaction with cysteine and 75 per cent sulphuric acid in Stumpf's modification[2] was applied to an equivalent amount of filtered urine. The spectral character of the colour formed was determined, together with the extinction at the wave-length of maximum absorption. For qualitative evaluation substances isolated from the urine with active charcoal were analysed by paper chromatography and detected using absorption in ultra-violet light and the reaction for deoxyribose and its compounds[3]. R_F values for the substances detected and standards were compared and absorption spectra determined for identification purposes. For quantitative data an equivalent amount of urine analysed chromatographically on Whatman paper No. 3 and substances containing deoxyribose were determined in an aqueous eluate using Dische's reaction[2].

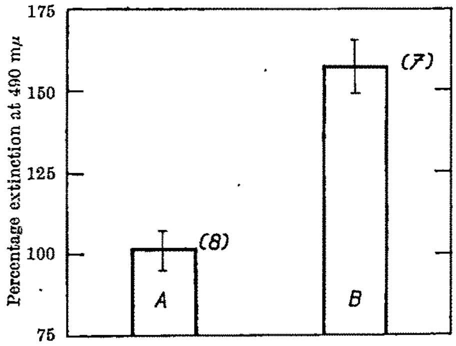

Fig. 1. The effect of irradiation on the excretion of Dische-positive substances in urine. Extinction at the wave-length of maximum absorption (490 mµ) in the urine of A, control rats ; B, irradiated animals. Urine was collected during the first 24 hr. after irradiation with a dose of 300–600 r. and adjusted to a constant volume

In the first experiments a total dose of 300–600 r. was applied. It is evident from Fig. 1 that irradiation causes an increased excretion of substances containing deoxyribose. The colour that arises has a characteristic maximum of absorption at 490 mµ. This increased excretion of substances containing deoxyribose is absent in the urine of animals stressed in other ways (partial restraint, multiple fractures of both hind limbs, injection of formaldehyde into the plantar region of both hind limbs, traumatization in the Noble–Collip drum and burns of the third degree in the lumbar region). This increased excretion of substances containing deoxyribose after irradiation was observed both in animals in metabolic cages fed with normal diet and in those animals that after irradiation had no access to food for the whole period of collection of urine. The excretion of these substances was also found after irradiation of female animals. Further work is required to determine whether there are quantitative differences in the amount excreted between the sexes.

An attempt was made to identify the substances containing deoxyribose that are excreted in increased amount in the urine after irradiation. Using the method described to isolate the substance it was possible to identify it as deoxycytidine on the bases of R_F values, positive reaction for deoxyribose, release of cytosine by acid hydrolysis and spectral characteristics.

It was further necessary to determine the amount of deoxycytidine thus excreted and its relation to the dose of irradiation applied. In addition, the excretion of the deoxyriboside of the other pyrimidine base of deoxyribonucleic acid—thymidine—was also studied.

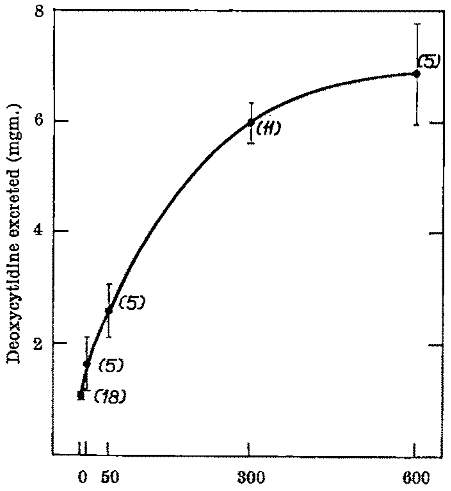

Fig. 2. Relation between the amount of deoxycytidine excreted and the irradiation dose. Urine excreted during 24 hr. was adjusted to a constant volume and an aliquot part analysed by paper chromatography. The part of the chromatogram containing deoxycytidine was eluted and deoxycytidine determined in the eluate colorimetrically (ref. 2). Averages and standard errors are shown

Results are summarized in Fig. 2. It could be shown that within a certain dose-range the intensity of excretion of deoxycytidine depends on the dose of irradiation used during the first 24 hr. after irradiation. On the other hand, it was found that irradiation within a certain dose-range has no analogous effect on the amount of thymidine excreted in the urine during the first 24 hr. after irradiation. Values for the latter substance were on the pre-irradiation level.

Excretion of deoxycytidine after irradiation offers new possibilities in the study of the effect of ionizing radiations on metabolism. From that point of view it is thought to be of importance to attack the problem of the causes for release of deoxycytidine after irradiation. Preliminary experiments showed that this excretion is not due to a renal factor, for in nephrectomized animals irradiation results in accumulation of substances containing deoxyribose in the body. This indicates that irradiation causes either increased release of deoxycytidine from deoxyribonucleic acids or that this substance accumulates as a result of a stop in the synthesis of deoxyribonucleic acid.

It is therefore of interest that a corresponding amount of the other pyrimidine deoxynucleoside, thymidine or its compounds, could not be demonstrated in the urine after irradiation. Consequently, in future work the role of thymidine and its derivatives will be studied together with their metabolic fate in relation to the effects of ionizing irradiation.

Excretion of deoxycytidine in the urine after irradiation also offers a new possibility for determining the degree of damage due to ionizing radiation both quantitatively and qualitatively, since within a certain dose-range the intensity of the reaction depends on the dose. Damage can be detected earlier and much more simply than with the diagnostic methods in use at present. It is of importance that excretion of deoxycytidine could also be demonstrated after low irradiation doses.

It may be expected that the excretion of deoxycytidine can thus become a new sensitive indicator of post-irradiation changes. It may further be useful in evaluation of protection against ionizing radiation.

Anæsthesia and the Action of DDT on *Anopheles* Larvæ

Between 95 and 100 per cent of newly moulted fourth-stage larvæ of *Anopheles quadrimaculatus* Say (LTD strain, Diptera, Culicidae) die within 24 hr. after a 10-min. exposure to massive doses of suspended DDT (1 : 10,000, 1 per cent acetone)[1]. The purpose of this communication is to direct attention to a very remarkable decrease in mortality of newly moulted larvæ to DDT when they have been anæsthetized with ether or carbon dioxide just prior to testing.

In the first series of experiments, 1-hr. old fourth-stage larvæ of *A. quadrimaculatus* were divided into two groups. Those in the first group were briefly rinsed in distilled water and placed individually in glass stoppered vials containing 5 ml. of 3·75 per cent ether in distilled water where they were left for 10 min. They were removed, washed in distilled water and transferred to freshly prepared acetone suspensions of DDT (10^{-4}) by means of fine cardboard tips. Following exposure to DDT, the larvæ were washed in two 1-l. changes of distilled water and finally placed in small numbered observation beakers containing food and water. The still anæsthetized larvæ were carefully oriented at the air–water interface. The second group was not anæsthetized prior to exposure to DDT. In a subsequent series of experiments larvæ were individually exposed to carbon dioxide gas in a small Erlenmeyer flask for 2 min. prior to treatment with DDT for 5 and 10 min., while controls received no treatment with carbon dioxide.

It is apparent from the results in Table 1 that anæsthesia significantly alters the mortality of larvæ to massive doses of DDT. The differences between ether and carbon dioxide are probably related to the fact that ether gives a deeper and much more prolonged anæsthesia.

The protective effect of anæsthesia is not due to failure of anæsthetized larvæ to eat the DDT drop-

Table 1. Effects of Ether and Carbon Dioxide Anæsthesia on the Mortality of 1-hr. old, Fourth Stage Larvæ of *Anopheles quadrimaculatus* Say to DDT (10^{-4}). Four to Eight Larvæ per Test (Average Five)

Treatment	No. of tests	Percentage dead at 24 hr.
Half-saturated ether for 10 min. before DDT for 10 min.	12	17·9
Controls in DDT 10^{-4} for 10 min.	12	100·0
Carbon dioxide for 2 min. before DDT for 5 min.	5	20·0
Controls in DDT for 5 min.	4	56·3
Carbon dioxide for 2 min. before DDT for 10 min.	5	74·0
Controls in DDT for 10 min.	5	96·0

lets, for DDT affects unanæsthetized larvæ far too rapidly for this to be the case. Nor can it be due to the failure of larvæ to encounter a sufficient number of DDT particles since anæsthetized larvæ which are drawn about within the suspension by cardboard tips are entirely comparable to those left completely quiescent.

The results suggest the intriguing possibility that initially DDT is either actively attached to the cuticle or is actively transported across it. Whatever the final explanation, it is clear that ether anæsthesia, in particular, interferes in some important way with the obtainment of a lethal dose of DDT.

Fate of Beta-Sitosterol in Housefly Larvæ

TWENTY different species of insect larvæ, distributed among four orders (Orthoptera, Coleoptera, Lepidoptera and Diptera) have been found so far to require sterols as growth factors. All of them, excepting the Dermestidae (*Dermestes vulpinus* Fabr.[1] and *Attagenus piceus* Oliv.[2]), can utilize both zoosterols and phytosterols; certain species, however, grow faster with dietary cholesterol than with a phytosterol[3]. Furthermore, the activity of the intestinal sterol esterase of *Periplaneta americana* L. was found to be limited to the esters of cholesterol, Δ^7-cholestenol and 7-dehydrocholesterol as the substrate[4]. These observations, together with Bergmann's[5] report on the cholesterol content of the phytophagous silkworm *Bombyx mori* L., led us to suspect that the dietary phytosterols are converted to a zoosterol before utilization. Hence, sitosterol conversion was investigated in the larva of the housefly.

Larvæ of *Musca vicina* Macq. were grown to pupation in an axenic culture with *Escherichia coli*, on a mixture of 40 per cent wheat bran and water. The sterols of the culture medium were identified by the isolation of their acetyl derivatives, which, after recrystallization first from 50 per cent ethanol and then ether, melted at 127·5–128·5° C., the melting point of β-sitosteryl acetate. The ultra-violet spectrum and the slow response to the Liebermann–Burchardt reagent proved the absence of conjugated double bonds. Also, the infra-red spectrum was identical with that of β-sitosteryl acetate.

In order to discover whether the sitosterol was transformed by the larvæ to cholesterol, we used the observation of Fraenkel and co-workers[1] that larvæ of *Dermestes vulpinus* Fabr. (*D. maculatus* Deg.) are unable to grow in the presence of plant sterols such as sitosterol, ergosterol and zymosterol, and develop into normal adults only if their food contains either cholesterol or 7-dehydrocholesterol. Our experiments have had the following results:

(1) Newly hatched larvæ of *D. vulpinus* or *D. cadaverinus* Fabr. (*D. ater* Deg.) developed into adults within 26–30 days (temperature 28° C., relative humidity 70 per cent) on ground dried pupæ of *Musca vicina* which had been reared as mentioned previously.

(2) The dermestid larvæ failed to grow and died in their first instar on a diet composed of 78 per cent ground housefly pupæ which had been extracted exhaustively with acetone and chloroform, of 10 per cent dried yeast extract, 11·5 per cent water and 0·5 per cent Nipagin *M*.

(3) Addition of 0·3 per cent cholesterol to this inactive mixture restored the nutritional value it had before the extraction, while neither the addition of the sterol isolated from the diet of housefly larvæ nor authentic β-sitosterol promoted the growth of the larvæ.

(4) The sterol of the housefly pupæ satisfied the sterol requirement of *D. vulpinus* and *D. cadaverinus*; the larvæ developed into normal hide beetles within 30–33 days on the extracted diet, supplemented with 0·3 per cent sterol of fly pupæ.

These results indicate that the larvæ of *M. vicina* convert, at least to some extent, dietary sitosterol into a sterol which is nutritionally equivalent to cholesterol or 7-dehydrocholesterol in *Dermestes* larvæ.

For the sake of comparison, some experiments have been carried out with powders of dried phytophagous insects, namely, pupæ of *Colias hyale* Godt. collected from various kinds of Leguminosae, and larvæ of *Orgyia antiqua* L. picked from their food plant *Polygonium equisetiforme*. Larvæ of *D. vulpinus* were able to complete their life-cycle on powders of both insects within 25–28 days, thus proving that these insects convert the phytosterols of their diet into zoosterols, utilizable by *Dermestes* larvæ.

Recently, Beck and Kapadia[6] have reported that larvæ of *Tribolium confusum* Duv. are capable of converting sitosterol and ergosterol into sterols resembling, or identical with, cholesterol and 7-dehydrocholesterol. While in this case the ingested sterols were metabolized almost completely, apparently only a small percentage of the sitosterol need be converted into cholesterol by the housefly larvæ. Our experiments indicate that the pupæ still contain considerable amounts of the original β-sitosterol.

It follows that the larvæ of *Musca* and *Orgyia* and the pupæ of *Colias* are capable of eliminating the 'supernumerary' carbon atoms of the phytosterol side-chain and convert the phytosterols to the skeleton of cholesterol. The larvæ of *Dermestes* are incapable of carrying out this reaction. This biological degradation is the more interesting as it has recently been shown[7] that the biosynthesis of ergosterol proceeds via cholesterol, into which the additional methyl group is introduced by means of methionine (the same is true for the methylene-branching in the side-chain of eburicoic acid[8]).

Thanks are due to Pest Infestation Laboratories, Slough, Bucks (England), for a supply of pupæ of

D. vulpinus, and to Dr. H. Bitinsky-Salz for the identification of *D. cadaverinus*. This work forms part of a Ph.D. thesis, submitted by one of us (Z. H. L.) to the Hebrew University, Jerusalem.

Cytotoxicity of Heterologous Sera to Normal and Leukæmic Human Lymphocytes

THEORETICALLY, cancer therapeutic agents should be able to differentiate between malignant and normal human cells and should be more toxic to the malignant cells. However, human leukæmic lymphocytes and cancer cells did not show, in *in vitro* studies[1,2], any greater sensitivity than normal cells to X-rays and chemotherapeutic agents. These disappointing results led to tests on the capacity of heterologous sera to discriminate between cells.

The slide chamber method[3] was used to determine the survival of normal and leukæmic lymphocytes in a medium composed of equal parts of test sera and of *TC* 199. The term 'leukæmic lymphocytes' is used to designate the lymphocytes from the blood of patients with chronic lymphogenous leukæmia. 'Normal lymphocytes' were derived from the blood or lymph nodes of non-leukæmic patients, most of whom had only minor disabilities. The serum of each rabbit was tested separately within ten days after bleeding. The number of viable lymphocytes were counted 2 hr. after incubation at 37° C. and once a day thereafter. An early positive toxic reaction was defined as one in which 90 per cent of the lymphocytes were killed in 24 hr.

Table 1. TOXICITY OF RABBIT SERA AND OF INACTIVATED GUINEA PIG SERA TO NORMAL AND LEUKÆMIC LYMPHOCYTES

Source of: Sera	Source of: Lymphocytes	No. of tests	Percentage of tests, 10 per cent survival time (days): 0–1	1–3	3–5	5–14
22 Rabbits	15 leukæmic patients	110	46	20	15	19
11 Rabbits	12 non-leukæmic patients	30	3	3	30	63
10 Rabbits	Leukæmic patient 'WOZ'	18	61	28	11	0
8 Rabbits	Leukæmic patient 'SOD'	11	36	0	27	36
Rabbit *B*	13 leukæmic patients	19	84	11	5	0
Rabbit *C*	9 leukæmic patients	10	0	20	40	40
Rabbit *B*	8 non-leukæmic patients	8	13	0	37	50
13 Guinea pigs	11 leukæmic patients	34	0	71	26	3
9 Guinea pigs	9 non-leukæmic patients	25	0	4	48	48
33 Non-leukæmic patients	17 leukæmic patients	36	0	0	0	100
17 Non-leukæmic patients	18 non-leukæmic patients	18	0	0	0	100

The rabbit sera gave early toxic reactions in 46 per cent of 110 tests on lymphocytes from 15 leukæmic patients (Table 1) and in 3 per cent of 30 tests on normal lymphocytes. The median 10 per cent survival time of non-leukæmic lymphocytes was 9·5 days when the cells were in human sera and 5·7 days in rabbit sera. Evidently, the rabbit sera were frequently rapidly toxic to leukæmic lymphocytes but usually had only a delayed toxic effect on normal lymphocytes.

The variability of the results is exemplified in Table 1 by the results on the cells of patients 'WOZ' and 'SOD' and on the sera of rabbits *B* and *C*. The complete data indicated that rabbits differed in the toxicity of their sera to leukæmic lymphocytes, that leukæmic patients differed in the sensitivity of their blood lymphocytes to the toxic sera, and that the sera of some rabbits differentiated between normal and leukæmic lymphocytes in a high percentage of tests.

Observations with an inverted phase microscope indicated that sensitive leukæmic lymphocytes in rabbit sera died by 'fixation', a process similar to that seen in lymphocytes irradiated with 10,000 r.[4]. In contrast, the normal lymphocytes in rabbit sera died by the development of intranuclear vacuoles and pyknosis, which has been studied by cinemicrography[5]. Normal granulocytes and erythrocytes, unlike normal lymphocytes, were sensitive to rabbit sera and lysed within an hour.

Early experiments with guinea pig sera gave the unexpected finding that leukæmic lymphocytes were frequently more sensitive to inactivated (56° C., 30 min.) than to fresh sera. The inactivated guinea pig sera gave a short (1–3 days) 10 per cent survival time in 71 per cent of tests with leukæmic lymphocytes and in only 4 per cent with normal cells.

The present results showed that, on the average, human leukæmic lymphocytes were sensitive to toxic factors in normal rabbit sera and in inactivated guinea pig sera. The rabbit sera usually killed the leukæmic lymphocytes in a few hours by 'fixation' and killed normal lymphocytes in a few days by intranuclear vacuolization. The rabbits differed in the toxicity of their sera and the leukæmic patients varied in the sensitivity of their lymphocytes to the toxic factors.

This work was aided by grant *CY* 2476 (*C*2) from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service. The leukæmic patients were made available through the kindness of Drs. I. A. Friedman, L. A. Baker and William Donnelly.

Influence of Circulating Adrenocorticotrophin on the Pituitary Adrenocorticotrophic Response to Stress in the Adrenalectomized Rat

REMOVAL of the adrenal glands results in a rise in the level of adrenocorticotrophic hormone in the blood of the rat. Cox and Hodges[1] reported that this increase did not occur until two weeks after adrenalectomy and that, after three to five weeks, there existed a remarkably high concentration of circulating hormone. These results were not inconsistent with the findings of Fortier[2], who showed that adrenalectomy caused a marked increase in the pituitary content of adrenocorticotrophic hormone after a similar time-lapse. It appears that there is an interval of at least two weeks before the rat pituitary gland adapts itself to secrete and maintain this enormously increased output of adrenocorticotrophic hormone in response to the absence of circulating corticoids. Therefore, it was of interest to compare the response to stress in adrenalectomized rats with low blood levels of corticotrophin with that in adrenalectomized animals with high blood levels of the hormone.

Adrenalectomized female Wistar rats were subjected to the stress of ether anæsthesia for 2½ min. at various times after the removal of their adrenal glands. The animals were decapitated, blood was collected from their trunks, injected intravenously into assay rats treated with hydrocortisone and its ability to produce depletion of adrenal ascorbic acid (which is a measure of its adrenocorticotrophic hormone content) determined, as described by Cox, Hodges and Vernikos[3]. The results were compared with those obtained using control adrenalectomized rats which were bled without being subjected to any previous stress. The results are summarized in Table 1.

It may be seen from Table 1 that exposure to ether vapour results in a marked increase in the circulating level of adrenocorticotrophin in the adrenalectomized rat. Furthermore, in contrast to the resting-level, the blood concentration of adrenocorticotrophic hormone after stress is independent of the time-lapse after adrenalectomy. The greatest increases occurred in the rats with the lowest initial levels of the hormone.

These results cannot be explained on the basis that the stores of corticotrophin in the pituitary gland become progressively exhausted after adrenalectomy, since several workers[2,4,5] have shown that removal of the adrenal glands results in a marked increase in the pituitary corticotrophin content. It appears more likely that the secretion of adrenocorticotrophin may be suppressed by a pre-existing high level of the hormone in the blood. The existence of such an 'auto feed-back' mechanism was also suggested by Kitay, Holub and Jailer[6], who found that the administration of exogenous corticotrophin to adrenalectomized rats prevented the usual fall in pituitary corticotrophin induced by stress. Thus, it appears that the circulating level of adrenocorticotrophic hormone may be yet another factor which may influence its release from the adenohypophysis.

Table 1. ADRENAL ASCORBIC ACID DEPLETIONS IN RATS TREATED WITH HYDROCORTISONE AFTER INTRAVENOUS INJECTIONS OF BLOOD FROM STRESSED AND NON-STRESSED ADRENALECTOMIZED RATS (3 ML./100 GM. BODY-WEIGHT)

Adrenal ascorbic acid level in saline-injected controls was 500 ± 10 mgm./100 gm. The figures in brackets indicate the number of animals injected

Time interval after adrenalectomy (days)	Mean ascorbic acid depletion (mgm./100 gm. adrenal tissue ± standard error)	
	Non-stressed	Stressed (ether 2½ min.)
5	−8 ± 13 (6)	126 ± 6 (12)
10	34 ± 8 (6)	146 ± 5 (12)
25	79 ± 8 (42)	139 ± 7 (6)
35	72 ± 12 (6)	155 ± 8 (6)

The expenses involved in this work were defrayed by a grant from the Medical Research Council, to which we are grateful.

Effect of some Lytic Agents on *Aerobacter aerogenes*

IN the course of a study of the surface structures of *Aerobacter aerogenes* the action of lysozyme has been investigated. Preliminary experiments indicated that the enzyme produced no observable changes in the optical density of cell suspensions. In an attempt to promote enzymic attack the conditions were varied by altering the concentration of lysozyme, the time and temperature of incubation, the origin and age of the bacteria, and the *p*H of the suspensions. Cells were also incubated with lysozyme and various concentrations of sodium chloride, magnesium chloride, versene[1] and *tris*-buffer[2]. No lysis which could be attributed to the action of lysozyme was observed under any of these conditions. Microscopic studies showed the appearance, in solutions containing 20 per cent sucrose, of spherical bodies, which were probably similar to the protoplasts obtained by Weibull[3] from *B. megatherium*. These, however, did not constitute more than 1 per cent of the cell population, except in one case, when bacteria incubated overnight with a 2 per cent solution of lipase were subjected to the action of lysozyme in 20 per cent sucrose. About 5 per cent conversion to spheres was observed. In a test for the presence of lysozyme substrate in the cell walls of *Aerobacter aerogenes*, washed cells were suspended in saline at *p*H 3·6 and incubated for 1 hr. at 40° C. with 200 μgm./ml. of lysozyme[4]. The optical densities of the suspensions were measured before and after incubation. The *p*H was adjusted to 10·0 by the addition of sodium hydroxide and the optical density measured immediately. A comparison with the results of a similar experiment in the absence of the enzyme showed that there was some lysis due to lysozyme. The specific substrate is thus present in the cell walls of the organism, but it is doubtful whether the amount available to the enzyme is sufficient to permit extensive lysis.

Lederberg[5] described the preparation of protoplasts from cells of *Escherichia coli* by allowing them to divide

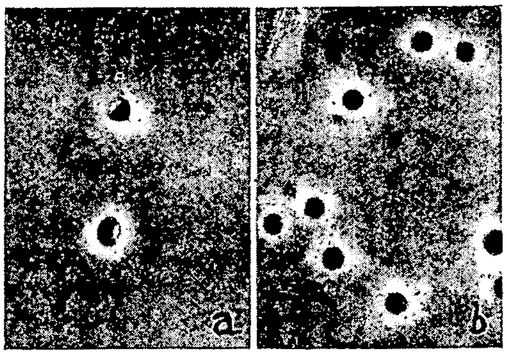

Fig. 1. Spherical bodies of *Aerobacter aerogenes* in 1·0 *M* sucrose (*a*) and in 0·2 *M* sucrose (*b*). (× 1,000)

in the presence of high concentrations of penicillin in a stabilizing medium. It was found that cells of *Aerobacter aerogenes* growing in a simple synthetic medium were lysed by 500 units/ml. of penicillin. However, cell division was suppressed by the high concentrations of sucrose or electrolyte necessary for the survival of any protoplasts formed. The organisms were able to grow and divide normally in 'Lab-lemco' broth containing 20 per cent sucrose. Accordingly, 200 ml. of an overnight broth culture was added to 600 ml. of broth containing sucrose (final concentration 0·6 *M*) and penicillin (1,000 units/ml.). After incubation for 3 hr. at 37° C. with gentle shaking, all the rapidly growing rod-shaped bacteria were converted to spheres. These were fragile to thermal, osmotic and mechanical shock. They could be harvested by centrifugation in the cold and resuspended in solutions of high osmotic pressure, for example, sucrose, glucose, sodium chloride or mixed phosphate buffers. By suspending the spheres in various solutions of sucrose at *p*H 6·8 and determining the concentrations which just prevented lysis at 25° C., their internal osmotic pressure was estimated at 5–6 atmospheres. The osmotic pressure of these bodies, which probably represents the mean osmotic pressure of the cells, is similar to that of *Escherichia coli*[6] and low compared with that of Gram-positive *Staphylococcus aureus* (25–30 atmospheres)[7].

There is some evidence that the spherical transformation undergone by rod-shaped bacteria exposed to the action of penicillin produces bodies the surface of which consists of material which can be differentiated from the cytoplasmic membrane. The spheres can undergo reversible plasmolysis when subjected alternately to high and low (5 atm.) external osmotic pressures in solutions of sucrose or sodium chloride. In concentrated solutions the protoplasm contracts away from the spherical shell surrounding the body. Addition of water causes it to expand until the sphere is filled completely (compare Figs. 1*a* and *b*). Evidently the protoplasmic membrane can become detached from the outermost material. These findings were confirmed by turbidity measurements. They are also in agreement with the observation made by Tomcsik[8], who found traces of cell-wall material on the spherical bodies obtained from *B. anthracis* treated with penicillin. It appears, therefore, that the term 'protoplasts' must be applied cautiously to such spherical bacterial bodies if it implies the complete absence of cell-wall material. Penicillin, while interrupting the biosynthesis of the main part of the cell wall, permits the formation of a fragmentary structure, which is unable to confer rigidity on the bacterial cell.

It is hoped to carry out electrophoretic studies on these bodies in an attempt to characterize their surface. Full details of these and other studies will be reported later.

We acknowledge gratefully continued financial support by the British Empire Cancer Campaign.

Release of Histamine from Mast Cells by Tissue Extracts

IT is now established that the mast cells are an important source of histamine in the body[1]. Histamine can be released from these cells *in vivo* by the injection of certain substances, such as compound 48/80 [2] and distilled water[3], but the mechanism of its release in pathological conditions, such as anaphylaxis and tissue injury, has not yet been satisfactorily explained. This problem has been investigated by exposing isolated mast cells from the rat to tissue extracts. It was found that injured nucleated cells produce a factor which liberates histamine from mast cells with histological changes in the mast cells varying from cellular swelling to cellular disintegration.

The mast-cell suspensions were prepared by injecting 40 ml. of physiological saline solution into the peritoneal cavity of the rat and aspirating the fluid after approximately 30 sec. Cellular elements were concentrated by centrifuging the aspirate. The mast cells were separated by layering the cellular concentrate on top of a 4-cm. column of 50 per cent albumin solution in a Wintrobe hæmatocrit tube and centrifuging the tube at 250*g* for 5 min. The mast cells were recovered from the bottom of the tube and were found to be almost free of other types of cells, which remained above the albumin layer.

Histamine was measured by the colorimetric method of Lowry *et al.*[4]. It was found that histamine was released from these mast cell preparations by mechanical grinding, by the addition of distilled water, and by the addition of compound 48/80 (20 μgm./ml.) protamine (10 μgm./ml.), *d*-tubocurarine (1 mgm./ml.) and peptone (1 mgm./ml.). Approximately 40 mgm. of histamine was obtained per million mast cells.

Histamine was also released from mast cells by saline extracts of spleen, kidney, liver and lung tissue from the rat and the rabbit. Histamine was released by saline extracts of pigeon red cells and of human white cells, but not by extracts of human or rat red cells. The extracts were prepared by grinding the tissue in an equal volume of physiological saline solution and incubating the homogenate at 37° C. for 30 min. Cell debris was removed by centrifugation. The active principle in splenic extract was not destroyed by boiling and was not removed by centrifugation at 28,000*g* for 30 min. It was stable in acid (0·25 *N* perchloric acid for 15 min. at 90° C.) and in alkaline solution (0·3 *N* potassium hydroxide for 24 hr. at 20° C.). Dialysis of the neutralized acid-treated extract against distilled water produced a precipitate which contained the active principle and gave a positive Sakaguchi reaction for arginine, a positive biuret reaction, and a negative reaction for carbohydrate. These findings suggest that the active principle is a long-chain polypeptide containing arginine.

Preliminary (unpublished) experiments have been performed in collaboration with K. Ellem, in which mouse ascites tumour cells and fresh antisera prepared in rabbits against the tumour cells were incubated for 30 min. at 37° C. A substance appeared in the serum which caused disintegration of mast cells with liberation of histamine. When non-immune rabbit serum was substituted for the antiserum, histamine was not released. In association with W. R. Sobey a similar phenomenon was observed with human white cells and fresh anti-human white cell serum prepared in rabbits (unpublished).

These experiments *in vitro* with mast cells suggest that injured nucleated cells produce a factor which leads to the disintegration of mast cells and the release of histamine. The active principle derived from injured cells appears to be an arginine containing polypeptide. The same mechanism may be responsible for the release of histamine when cells are injured *in vivo*.

Inherited Hypertension in Rats

During the past eight years a colony of hypertensive rats has been developed by breeding from rats with over-average tail blood pressures. The mean blood pressure of the Otago rat colony from which rats were selected for breeding is of the order of 124 mm. mercury for bucks, 116 mm. mercury for does.

We have developed several families with a high incidence of hypertension by selective cross-breeding, and in three strains (*A*, *B* and *C*) by intensive inbreeding, using brother–sister mating. Selective cross-breeding has produced higher pressures than inbreeding (Fig. 1).

Comparison of blood-pressure levels of unanæsthetized rats, gently restrained, and of the same rats under light ether anæsthesia revealed no important difference in the means. The average blood pressures of 70 rats, some hypertensive and some controls, without anæsthesia was 131·9 and under light ether anæsthesia was 129·8 mm. mercury. Direct recording of pressures with a tube in a femoral artery disclosed great variability in the blood pressure of the rat, both under anæsthesia and unanæsthetized. While there is a close relationship between tail pressures and direct pressure readings from a femoral artery, the fluctuations of the blood pressure-level make it necessary to obtain readings on several occasions for each rat in order to obtain an average value.

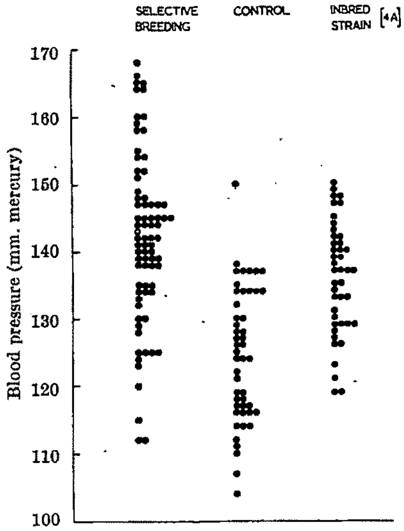

Fig. 1. Blood pressures of rats with inherited hypertension as compared with control rats. Each dot represents the average of several readings in a rat

The general impression is that we can expect at least 30 per cent of buck rats in the Otago hypertensive colony to have tail pressures exceeding 140 mm. mercury. In strains cross-bred selectively we may reasonably expect more than 10 per cent of bucks to have pressures exceeding 150 mm. mercury and occasional bucks to have pressures of 160–170 mm. mercury.

The average pressure of 50 control buck rats measured recently was 124·14 (standard deviation 10·64) mm. mercury; of 43 buck rats of strain *A*, 135·81 (standard deviation 8·20). The difference of the means is about five times the standard error of difference (1·96) and highly significant. The mean blood pressure of 76 selectively cross-bred buck rats was 141·95 (standard deviation 12·53) mm. mercury, which is 17·81 mm. mercury greater than the mean for control rats. The difference of the means is in this case more than eight times the standard error of difference (2·08).

The selectively bred does have a mean pressure of 135·37 and the fourth generation of the *A* inbred strain 129·91, as against 116·33 mm. mercury for the Otago control colony. The differences of the means are in each case more than five times the standard errors of difference and therefore highly significant.

Some results will be published later by Dr. Arthur Veale relating the blood pressure as estimated by the tail method in the rat to the width of cuff, use of ether anæsthetic, absence of an anæsthetic, position of the cuff and recorder on the tail, direct warming of the tail, use of a thermostatically controlled room, etc. We are indebted to Mr. C. Drake, Dr. I. Eryetishir and Mrs. R. Shacklock for some of the blood-pressure readings.

Influence of the Thymus upon the Reaction of the Rat to Anterior Pituitary Growth Hormone

A relation between the thymus and the growth hormone of the anterior pituitary has been assumed by many authors. It is known that injections of this hormone result in an enlargement of the thymus[1]. A more thorough investigation of the interaction between these two glands seemed of interest.

80 male rats of 130–160 gm. were used. They came from a local inbred strain. The animals were divided into the following groups: (*A*) 20 animals were hypophysectomized by the method of Smith, as described by Farris and Griffith[2]; (*B*) 60 animals were thymectomized by the method of Segaloff[2] and hypophysectomized 8 days later.

Following hypophysectomy, the animals were kept at a constant temperature of 29° C. Growth was recorded for 15 days by daily weighing to the nearest 0·5 gm. The hormone injections were begun the 16th day after hypophysectomy: (*a*) the 20 hypophysectomized animals received daily injections of a commercial growth hormone preparation at daily doses of 0·5, 1·0, 2·0, 3·0 and 4·0 Evans units (4 animals at each dose); (*b*) 20 animals from the thymectomized and hypophysectomized group received the same injections; (*c*) 20 thymectomized and hypophysectomized animals were injected daily with the thymus preparation of Bezssonoff and Comsa[3] at daily doses of 5, 10, 20, 35 and 50 guinea pig units[4] (4 animals at each dose); (*d*) 20 thymectomized and hypophysectomized animals were injected similarly with the same thymus preparation. The thymus injection was followed immediately by an injection of growth hormone at a dose of 2·0 Evans units in all animals. The injections were continued for 15 days with daily weighing.

During the 15 days between hypophysectomy and the first hormone injection, weight loss was constant in all animals. It amounted to about 12 gm. in both groups (1 and 2).

The results during the hormone-injection period are shown in Tables 1 and 2. It can be seen that: (1) in group *A* the growth-rate under the influence of the same dose of growth hormone was significantly smaller than in group *B*. (2) Thymus extract injections alone had no real influence upon the growth-rate of group 2 animals. The loss in weight observed in the preperiod ceased following the thymus injections, but no proper growth was observed. (3) The simultaneous injection of thymus extract and 2·0 Evans units of growth hormone resulted in a significant enhancement of the influence growth hormone upon the growth-rate.

Table 1. Influence of Daily Injections of Anterior Pituitary Growth Hormone upon the Growth-Rate of the Rat

Hormone daily dose (Evans units)	Weight difference after 15 days of daily injections (arithmetical average of three animals)	
	A Hypophysectomized	*B* Thymectomized and hypophysectomized
0 (preperiod)	−12·8 ± 3·0	−12·0 ± 1·0
0·5	0	−4 ± 1·0
1·0	15·0 ± 3·8	6·5 ± 2·2
2·0	30·0 ± 5·1	11·5 ± 2·0
3·0	41·0 ± 7·2	12·0 ± 3·0
4·0	56·0 ± 5·0	17·0 ± 3·0

Table 2. Influence of Daily Injections of Thymus Extract upon the Growth-Rate of Thymectomized and Hypophysectomized Rats

Thymus daily dose (units per rat)	Weight difference after 15 days of daily injections (gm., arithmetical average of three animals)	
	C Injected with thymus only	*D* Injected with thymus and 2·0 units of growth hormone
0	−12·0 ± 1·0	+11·5 ± 2·0
5	−8 ± 0·8	+30·0 ± 4·0
10	0	+45·0 ± 7·0
20	−0·5 ± 0·2	+58·0 ± 6·0
35	−3·0 ± 0·5	+64·0 ± 6·4
50	−1·5 ± 0·6	+80·0 ± 4·8

It can be concluded that the thymus is a significant factor in the growth effect of anterior pituitary growth hormone.

We are indebted to Miss L. Fehres for technical advice, and to Messrs. Choay (Paris) for growth hormone.

Synapse Discharge by Single Fibre in Mammalian Visual System

Following a single brief electrical shock applied to the optic nerve in the cat there is, from the lowest levels of stimulation, an approximately linear relation between the amplitudes of the pre- and post-synaptic responses recorded in the lateral geniculate body[1]. This was taken to indicate that only a small number of optic tract fibres are needed to discharge a geniculate cell.

In the course of recording extracellularly from single units in the visual pathways of the Dial-anæsthetized cat we have obtained further evidence in favour of this view. In the case of at least two geniculate cells that we have been able to study in some detail we conclude that they were each being discharged by a single optic nerve fibre. The evidence for this is illustrated in Figs. 1 and 2. Records *a* and *b* in Fig. 1 are representative of a large number obtained in the vicinity of a single geniculate cell in response to a stimulus of constant strength applied to the ipsilateral optic nerve; (*a*) consists of three and (*b*) of many superimposed oscillograph traces. It is clear that only three types of response are obtained: (1) a spike potential, (2) a synaptic potential (that is, an excitatory postsynaptic potential[2] recorded extracellularly) and (3) neither of these.

Our evidence that (2) is a synaptic potential is as follows: it always precedes the spike potential as a step on the rising phase; it has the time course of synaptic potentials obtained elsewhere[3]; it sums with a second such potential (Fig 1*e*); it shows progressive depression during a train of evoked responses (Fig. 1*e*), in this respect resembling the end-plate potential at the mammalian neuromuscular junction[4]. Finally, in recording from other single geniculate cells, we have found that *d*-lysergic acid diethylamide (*LSD* 25) abolishes the spike potential, leaving a potential which closely resembles response (2) of Fig. 1. A similar result can also be obtained by placing the test shock in the wake of a brief but rapid train of conditioning stimuli applied to the optic nerve. Fig. 3 shows the effect of a critical blocking dose of *d*-lysergic acid diethylamide, the response prior to the application of the drug being similar to (*b*). During the action of the drug the response varied between the two forms (*a*) and (*b*) of Fig. 3. A further dose of the drug abolished the spike potential and reduced the amplitude of response (*a*) without altering its time course. It has previously been concluded[5] that *d*-lysergic acid diethylamide blocks transmission in the lateral geniculate body by reducing the postsynaptic response to a non-propagating postsynaptic potential.

Our interpretation of the records in Fig. 1 is that the stimulus is critical for a single optic nerve fibre. If the fibre is not excited we obtain response (3), the electrical field response due to other activated fibres and cells; if the optic nerve fibre fires we obtain either response (1) or response (2), that is to say, the synaptic potential is about threshold for the discharge of the geniculate cell. There is no variation in response (2) beyond what is to be expected in the baseline itself under these recording conditions. The spike potential in response (1) arises from the synaptic potential with no detectable increase in amplitude of the latter. If another optic nerve fibre was needed for the cell to discharge then one ought to see an increment in the synaptic potential before the spike arose, and one ought also to see occasionally this second synaptic potential alone; neither was seen.

The spike potential does have another step on its rising phase (in the reproduced photographs clearly visible only in Fig. 1, where it is indicated by arrow). It is unlikely that this step represents a second synaptic potential summing with the first because it is always intermediate between the synaptic potential and the full spike and has a faster rising phase; if it were a synaptic potential one should occasionally see it either alone or initiating the full spike potential of its own accord.

It is not yet known to what degree synaptic activity in different parts of one cell can be recorded by an extracellular electrode. The possibility, therefore, of an unrecorded additional synaptic potential is difficult to exclude. However, in this case, the spike potential was never initiated except after the synaptic potential. This fact excludes the possibility of any other synaptic potential capable of firing the cell, and we feel that it is unlikely that synaptic potentials of any significance have gone unrecorded.

The records in Figs. 1 and 3 were obtained using glass capillary microelectrodes filled with 3 *M* potassium chloride, having a d.c. resistance of about 5 megohms. Those in Fig. 2 were obtained with a fine steel electrode insulated to the tip; records *a*, *b* and *c* are varying responses to a stimulus of constant strength. The remarks made in connexion with Fig. 1 apply also to this cell.

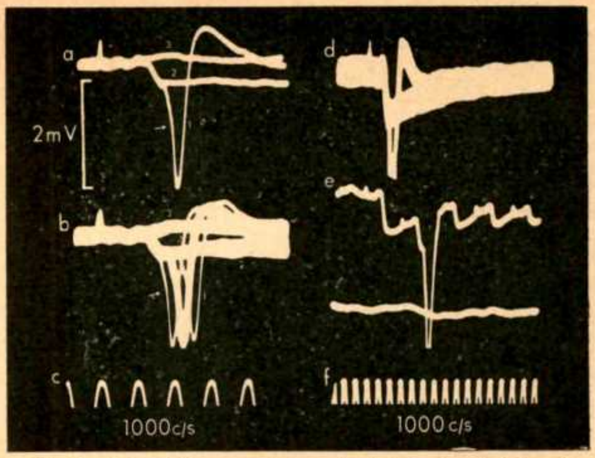

Fig. 1. Extracellular records from single lateral geniculate cell to electrical stimulation of ipsilateral optic nerve. (*a*) and (*b*) Stimulus of constant strength; (*a*) three and (*b*) many successive traces superimposed. Arrow indicates step on rising phase of spike potential. (*d*) Similar series later in the experiment. (*e*) Responses to a train of five stimuli at 300/sec. Time calibration (*c*) applies to (*a*) and (*b*), calibration (*f*) to (*d*) and (*e*). Voltage calibration applies to all records. Negativity upwards in all figures. Spikes truncated in (*d*) and (*e*)

Responses essentially the same as those depicted ing Figs. 1 and 2 have been described by Freygang[6], who also regards response (2) as a synaptic potential. It is not proposed here to enter into the questions of the polarity of the response nor of the exact site of origin of its various components. These have been discussed by Freygang[6].

Our results do not mean that geniculate cells are not also innervated by optic fibres which on their own are incapable of discharging an impulse in the postsynaptic element. We have occasionally observed synaptic potentials which could be graded to some extent by varying the strength of afferent stimulation (cf. Freygang[6]), and the existence of a subliminal fringe around geniculate cells is well established from other studies[7]. These results, however, indicate the existence of 'single-fibre straight-through' pathways in the lateral geniculate nucleus. Although, in the cases described here, the synaptic potential is of critical strength for impulse propagation, certainty would be assured in the unanæsthetized animal and

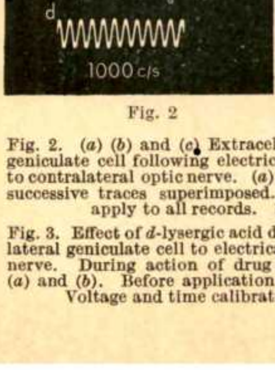

Fig. 2

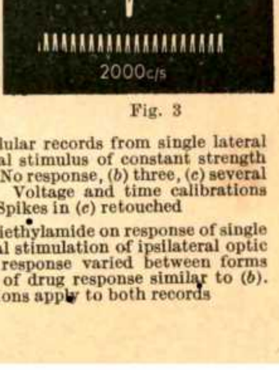

Fig. 3

Fig. 2. (*a*) (*b*) and (*c*) Extracellular records from single lateral geniculate cell following electrical stimulus of constant strength to contralateral optic nerve. (*a*) No response, (*b*) three, (*c*) several successive traces superimposed. Voltage and time calibrations apply to all records. Spikes in (*c*) retouched

Fig. 3. Effect of *d*-lysergic acid diethylamide on response of single lateral geniculate cell to electrical stimulation of ipsilateral optic nerve. During action of drug response varied between forms (*a*) and (*b*). Before application of drug response similar to (*b*). Voltage and time calibrations apply to both records

especially in response to the physiological stimulus of light, since the response in an optic fibre is then likely to consist of a brief high-frequency train of impulses.

This ability of single optic nerve fibres to discharge geniculate cells is almost certainly made possible by the fact that the preterminals branch very extensively[8], so that a single fibre may apply a large number of terminals to a cell. This property of the geniculate synapse is in sharp contrast to the spinal motoneuron, which integrates and acts as the final common path for impulses from a wide variety of afferents. This 'straight-through' property of many geniculate cells by no means excludes the possibility of important modifications in the signal taking place at this level, since changes can occur in the pattern of the repetitive discharge which frequently follows a single afferent volley[9].

Larval and Adult Hæmoglobins of the Cyclostome *Petromyzon planeri*

SYSTEMATIC investigations of the electrophoretic behaviour of hæmoglobins of various vertebrates have so far been carried out mainly on the higher forms. We have started to investigate the electrophoretic behaviour of hæmoglobin of the cyclostome *Petromyzon planeri* in the adult or in the ammocoetes stage.

Paper electrophoresis did not permit the detection of any consistent differences between adult and larval blood, which by this technique showed the same electrophoretic pattern consisting of a single hæmoglobin band migrating toward the anode. On the other hand, starch-gel electrophoresis provided evidence for the presence of two distinct hæmoglobin bands with different mobility at each stage.

Adult and ammocoetes of *Petromyzon planeri* were collected from the River Sarno near Naples. Blood from 32 adults and 44 ammocoetes has been examined. Blood was collected, by decapitation, in Alsever solution. Erythrocytes were washed repeatedly, and then hæmolysed with distilled water.

Electrophoresis was performed with starch gel using the discontinuous buffer system described by Poulik[1]. Fig. 1 shows the positions of all the hæmoglobin components in the adult and ammocoetes stages. Adult blood has two hæmoglobin bands (I and II). Hæmoglobin I migrates more rapidly and is present in much smaller amounts than II. Larval blood also has two distinct hæmoglobin bands (I′ and II′), which are apparently present in the same concentrations. They migrate more rapidly than the adult ones.

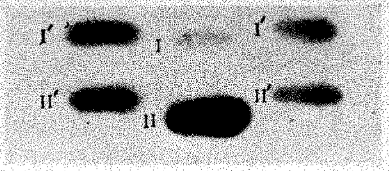

Fig. 1

Apart from the difference in the electrophoretic mobility between adults and larvæ, no other differences were detected among animals of the same stage and in particular no animals with only a single band were found in Nature.

It is conceivable, therefore, that the double-band pattern obtained only by gel electrophoresis might be the result of some kind of degradation of the hæmoglobin molecule due to the supporting medium itself.

Further researches are in progress to clarify this aspect of the problem, bearing in mind what is known for mammalian hæmoglobins[2-4].

Nevertheless we think that the results given above allow the conclusion that in these lower vertebrates the electrophoretic behaviour of hæmoglobin in the larval stage is different from that of the adult stage. Although this may be obviously interpreted as to be due to the presence of some fœtal-like hæmoglobin in the larvæ, it must be noted that unlike the mammalian fœtal hæmoglobin, here the larval hæmoglobin migrates faster than the adult one.

Respiration and Radiosensitivity of Broad Bean Roots

IN the root-tips of the broad bean, *Vicia faba*, potassium cyanide, hydrogen sulphide and cupferron (the ammonium salt of nitrosophenylhydroxylamine) increase the frequency of chromosome aberrations produced by a given dose of X-rays at very low oxygen pressures[1-3]. In the case of cupferron at least, the effect on radiosensitivity seems to be a result of its inhibitory action on the respiration of bean root tips[3]. The fact that oxygen enhances the radiosensitivity of the root-tip chromosomes of *Vicia faba* has been known since the studies of Thoday and Read[4]. When the roots are respiring normally an oxygen effect does not become evident until the concentration of oxygen in the gas phase exceeds 3 per cent, apparently because at lower concentrations oxygen is removed by respiration in the outer cells of the root, so that completely anaerobic conditions prevail in the central parts. When respiration is inhibited, oxygen is able to diffuse into the cells of the whole meristem, even in cases when the oxygen concentration outside the root is very low. That this is the correct explanation of the increased frequency of aberrations obtained in the presence of cupferron is indicated by the fact that cupferron has no marked influence on radiosensitivity in the complete absence of oxygen[3].

Unlike cyanide and sulphide, cupferron has not been known previously as a respiratory inhibitor. In experiments performed with the aid of the Warburg manometric technique, it has now been found that the respiration of excised bean root tips is markedly inhibited by cupferron. The effect is influenced by the *p*H of the solution and also, to some extent, by the oxygen pressure. A low *p*H and a low oxygen tension favour the inhibitory effect of cupferron. At an oxygen pressure of 2·8 per cent and a *p*H of 5·5, the inhibition produced by 400 μmoles/l. cupferron varies between 70 and 100 per cent. As appears from Table 1, there is a correlation between the effect of cupferron on radiosensitivity and its effect on respiration.

By using cupferron as a respiratory inhibitor, it has been possible to obtain a relation between oxygen pressure and the radiosensitivity of the root-tip chromosomes of *Vicia*, which approaches the true one more closely than that obtained when respiring root-tips are used. This relation is expressed graphically in Fig. 1. As a comparison, the relation between oxygen pressure and effect was also determined in the absence of cupferron and the resulting curve is included in Fig. 1.

Since preliminary X-ray experiments indicated that no further increase of radiosensitivity is obtained by decreasing the *p*H below 5·8 or by increasing the cupferron concentration above 400 μmoles/l., the *p*H was kept between 5·8 and 6·0 in subsequent experiments and the concentration of cupferron was 400 μmoles/l. Oxygen–nitrogen mixtures containing 0·1, 1·0, 2·8, 5·4 and 10·1 per cent oxygen were supplied by the Swedish Gasaccumulator Company. The other oxygen concentrations used in the experiments were obtained by mixing gases with known concentrations of oxygen in appropriate proportions by the aid of flow-meters. Oxygen-free nitrogen was obtained by passing tank nitrogen over active copper in a Meyer–Ronge column[5]. The gases were introduced into the 'Lucite' vessels used for the treatments through fritted glass filters. The beans were kept under anaerobic conditions for 10 min. before an oxygen-free solution of the inhibitor was introduced. The required oxygen–nitrogen mixture was then bubbled through the solution for 25 min. before the irradiation and the bubbling was continued during the irradiation itself. The X-rays were generated in a Müller therapy tube type 71780, operating at 180 kV., 5 m.amp. and filtered by 1 mm. of aluminium. The dose was 100 r. and the dose-rate 20 r./min. The beans were fixed 18 hr. after the irradiation. Permanent Feulgen-squashes were prepared as described previously[6].

It appears from Fig. 1 that, in the presence of cupferron, 1·3 μmoles/l. oxygen is enough to increase the radiosensitivity. The number of isolocus breaks and exchanges obtained per 100 cells under anaerobic conditions is more than doubled at an oxygen concentration of 3·9 μmoles/l., and at 36 μmoles/l. the maximum radiosensitivity seems to have been reached. In the absence of cupferron, no significant increase of radiosensitivity was obtained at oxygen concentrations below 65 μmoles/l. Fig. 1 also shows that the effect is considerably greater in the presence than in the absence of cupferron at high oxygen tensions. The explanation given above for the effect of cupferron on radiosensitivity does not seem to be applicable to the increased effect obtained at high oxygen tensions in the presence of cupferron. The latter may possibly be due to the radiomimetic effect of cupferron[7], although ½-hr. treatments with 400 μmoles/l. cupferron alone as a rule do not produce any chromosome aberrations.

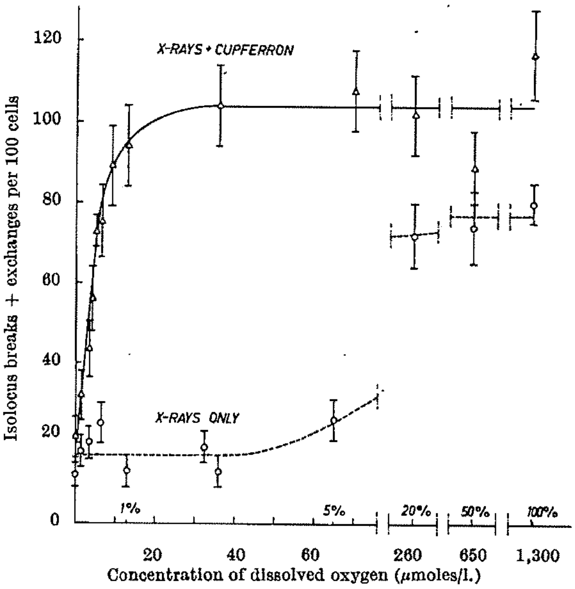

Fig. 1. The relation between the concentration of dissolved oxygen and the frequencies of chromosome aberrations induced by 100 r. of X-rays in the presence and the absence of cupferron

Table 1. THE EFFECT OF 200 μMOLES/L. CUPFERRON ON THE FREQUENCY OF X-RAY-INDUCED CHROMOSOME ABERRATIONS AND ON OXYGEN CONSUMPTION AT *p*H 5·5 AND 7·3

	X-ray experiments				Respiration experiments	
*p*H	Concentration of oxygen in the gas phase (per cent)	Abnormal metaphases (per cent)	Aberrations/100 cells		Concentration of oxygen in the gas phase (per cent)	Inhibition of oxygen consumption (per cent)
			Isolocus breaks	Exchanges		
5·5	1·0	68	52	50	2·8	83
7·3	1·0	22	9	15	2·8	11

The X-ray–cupferron curve in Fig. 1 is very similar to the curve obtained by Howard-Flanders and Alper for the radiosensitivity of the bacterium *Shigella flexneri* at different oxygen tensions[8]. In another series of experiments, the constants *m* ("maximum enhancement ratio") and *K* ("that oxygen concentration which will give $(m + 1)/2$ times the nitrogen radiosensitivity") of Howard-Flanders and Alper[8] were established. The value of *K* obtained in the presence of cupferron at 22° C., 4·2 ± 0·9 μmoles/l., is also very close to that obtained by Howard-Flanders and Alper for *Shig. flexneri*. In the absence of cupferron the value of *K* was found to be about 132 μmoles/l. Thus, when respiration is inhibited, the radiosensitivity of the root-tip chromosomes of *Vicia faba* is affected by a concentration of oxygen which is about thirty times lower than that effective in the absence of the inhibitor.

Occurrence of an Exotic Oligochaete *Branchiura sowerbyi* Beddard, 1892, in the River Thames

IN the course of a study of the bottom fauna of the River Thames just below Reading, a large population of *Branchiura sowerbyi* has been found among the roots of emergent aquatic plants such as *Carex acutiformis*, *Acorus calamus* and *Schoenoplectus lacustris*. Although samples have been taken from many parts of the River over a stretch of about two miles, all the specimens of *Branchiura* found hitherto have been from a region just below the warm water effluent of Earley power station. The distinctive characters of the worm are its large size compared with other members of the Tubificidae and the possession of filamentous gills on the mid-dorsal and mid-ventral lines of the posterior part of the body.

Branchiura sowerby was first described by Beddard[1], who found it in the mud of the *Victoria regia* tank in the Royal Botanic Society's garden in Regent's Park, London. It was later recorded from similar warm water tanks in Hamburg[2], Dublin[3], Kew and Oxford[4]. According to Stephenson[5], it is common in India, China, Japan and Java, and occurs in the Rhone and elsewhere in southern France, possibly as a result of being introduced with plants imported into gardens on the banks of the rivers. The first person to find *Branchiura* in a natural habitat in Britain was Dr. P. M. Jenkin, of the Zoology Department, University of Bristol. In a recent private communication, she described her findings as follows: "A small colony has persisted for five years on the Kennet and Avon Canal. The species has now appeared for the first time in the Bradford River Avon, at a spot where collections have been made for twenty years. Temperature records stored in the University of Bristol Zoological Department show no indication of warm effluents near either of these sites. The canal is so shallow that it must freeze in the winter. The worms live in organic mud under 4–6 inches of water. They survive well in the laboratory in tubes containing tap water and some mud from their natural environment."

The population of the worms in the Thames is not a small one, as it is estimated from quantitative samples that many thousands are present. They are obviously breeding very freely, and it seems likely that the warm water effluent of the power station (maximum temperature observed, 25° C.) is a more favourable habitat than the unheated waters of the Kennet and Avon Canal. On the other hand, the fact that the worm has appeared in a second unheated habitat suggests that it has become acclimatized sufficiently to be able to increase its numbers in a normal river. That being so, it may well spread through the river and canal system of Britain, and I would be most interested to hear of further records.

Histochemical Study of the Nasal (Supra-Orbital) Gland of the Duck

THE recent demonstration by Schmidt-Nielsen and co-workers[1,2] that in marine birds the nasal (supraorbital) glands can, under conditions of salt loading, excrete a strongly hypertonic solution of sodium chloride has brought added significance to a study of the comparative cytology and histochemistry of these glands in progress in this department.

In the domestic duck, which has well-developed nasal glands, no histological evidence has been found to support either of the two earlier views on the nature of the secretion of these glands. One widely held opinion has been that the glands elaborate a 'serous' secretion. In the duck gland, cytoplasmic ribonucleic acid, assessed by affinity for toluidine blue and for pyronin, is notably scarce; the secretory elements are, indeed, conspicuously eosinophilic. Moreover, 'zymogen' granules are absent. The other view[3], that the gland produces a slimy (? mucous) secretion, also has no histochemical support. No mucus-secreting elements can be demonstrated by the periodic acid – Schiff technique, or with Alcian blue staining, and there is no metachromatic staining with toluidine blue.

The positive findings of the present study are (1) an extraordinary abundance of mitochondria, which appear almost to fill the cytoplasm of the secretory cells; (2) a moderate content of lipoid which is unstained by sudan III and IV, well stained by sudan black and gives a positive reaction to Baker's acid hæmatein test for phospholipids (pyridine extracted controls give a negative reaction: it seems likely that the phospholipids are mainly mitochondrial); (3) a very abundant blood supply; and (4) moderate amounts of alkaline phosphatase (3 hr. incubation, Gomori technique) in the nuclei, and minimal amounts in the cytoplasm, of cells at the extreme periphery of each gland lobule.

In their eosinophilia and high mitochondrial content, the secretory elements of the nasal gland of the duck are strongly reminiscent of the oxyntic cells of the gastric glands of mammals and of the chloride-excreting cells of the gill of euryhaline fishes, both of which are usually thought to be involved in active secretion of chloride ions.

Preliminary experiments indicate that the nasal glands of the duck are normally inactive, but that under conditions of salt loading they secrete chloride at concentrations of up to 640 m.equiv./litre—a level comparable with that reported for the cormorant[1] and the penguin[2].

Cytochromes of *Nitrobacter*

A CYTOCHROME system appears to be involved in the oxidation of nitrite by *Nitrobacter* since, at normal temperatures, three cytochrome bands may be seen in suspensions of the cells in the presence of nitrite, but not in its absence. These are two sharp bands at 521 $m\mu$ and at 550 $m\mu$ and a more diffuse, less-intense band at about 589 $m\mu$ [1].

We have now obtained further indications of involvement of cytochromes in nitrite oxidation since the oxidation has been found to be inhibited by carbon monoxide and by cyanide. We have therefore carried out a more detailed examination of the cytochromes of *Nitrobacter*.

In the presence of aqueous glycerol (50 per cent v/v), at the temperature of liquid air[2], the band at 589 mμ was resolved into two separate bands at 598 mμ and at 580 mμ. The former band probably represents that of the cytochrome *a* component of the cells.

In order to determine the distribution of the cytochromes *Nitrobacter* cells were crushed in the Hughes press and whole cells removed by centrifugation at 4,000*g*. The cell-free suspension thus obtained was separated into an insoluble fraction and a cell extract by centrifugation at 15,000*g*. The insoluble fraction, with dithionite, showed all the bands present in the whole cells, whereas the extract contained only the cytochrome with bands at 521 mμ and 550 mμ.

When the cells were disintegrated with the Nickle shaker and fractionated by the method of Salton and Horne[3], a preparation was obtained which, by electron microscopy, was shown to consist of cell walls. The preparation was deep red in colour and appeared to contain all the cytochromes present in the whole cells; the extract of the cells, however, as in the case of the extract of cells crushed in the Hughes press, contained only the cytochrome with bands at 521 mμ and 550 mμ.

One of the cytochromes present in the insoluble fraction of the cells crushed in the Hughes press appears to have cytochrome oxidase activity. The soluble cytochrome of *Nitrobacter* is not autoxidizable, but addition of a suspension of the insoluble fraction to the cell extract renders this cytochrome oxidizable by air; the insoluble fraction also catalyses the oxidation of reduced mammalian cytochrome *c* by air. Cytochrome oxidase activity in the insoluble fraction could also be demonstrated manometrically with ascorbate[4]; the uptake of oxygen by this fraction in the presence of ascorbate was increased by the addition of either the soluble fraction of the cells or by mammalian cytochrome *c*. This observation indicates that the insoluble fraction is relatively deficient in *c*-type cytochromes (probably the cytochrome with bands at 521 mμ and 550 mμ) and that the cytochrome oxidase of the insoluble fraction is capable of coupling with mammalian cytochrome *c*.

The similarity between the 550 mμ cytochrome and mammalian cytochrome *c* was further demonstrated by examination of an extract from crushed cells partially purified by ethanol fractionation at 0° C.

The spectrum of the cytochrome was found[5] to be similar to that of mammalian cytochrome *c*, with the main bands in the reduced form at 550 mμ, 521 mμ and 416 mμ. The spectrum of the reduced pyridine hæmochromogen of the cytochrome was identical with that of mammalian cytochrome *c*.

The E'_0 of the cytochrome was determined by titration with ferrocyanide in the presence of ferricyanide in an atmosphere of nitrogen. It was found to be in the region of 0·25 V. at *p*H 7·5 and 25° C. The reduction of the cytochrome appeared to involve a single electron transfer since the slope of the graph of log ferrocyanide/ferricyanide against log reduced cytochrome/oxidized cytochrome was 45° C.

The isoelectric point of the cytochrome, determined by electrophoresis on paper with glucose as a marker to correct for electro-endosmosis, was found to be approximately 6·5. In this respect the *Nitrobacter* cytochrome appears to differ from mammalian cytochrome *c*, which has an isoelectric point[6] of 10·65.

Occurrence of Gentisic Acid in Plant Tissues

In the course of chromatographic studies on the phenolic constituents of *Theobroma cacao* L., an ultra-violet fluorescent compound (compound *A*), possessing an R_F value of 0·28 in benzene/acetic acid/water, was shown to be widely distributed throughout the tissues of the plant[1]. This compound has now been shown to possess chromatographic and ultra-violet fluorescence properties identical with those of gentisic acid (2 : 5 dihydroxy benzoic acid). Chromatographic examination of a large number of leaf hydrolysates has revealed that gentisic acid is widely distributed in the plant kingdom, and it would appear to be one of the most commonly occurring aromatic acids of plant tissue. This acid, although usually present in very small or trace quantities, can readily be detected by the chromatographic technique described. The presence of other fluorescent aromatic acids, namely, caffeic, ferulic and sinapic acids in leaf hydrolysates has recently been reported[2].

Although a good separation of compound *A* from the other fluorescent constituents of cacao leaf hydrolysates is effected by the use of the benzene/acetic acid/water system[3], the use of 20 per cent aqueous potassium chloride; *iso*propyl alcohol/ammonia/water[4] or chloroform/acetic acid/water[5] is rendered difficult by the fact that certain flavonoid and phenolic residues present in cacao extracts tend to conceal the gentisic acid spot. A preliminary separation was therefore carried out, the ethereal extract of the hydrolysate, prepared by the standard procedure[1] being applied to the chromatogram in a continuous band. After development with benzene/acetic acid/water the appropriate fluorescent band was cut out and eluted with hot methanol. The methanolic extract thus obtained was run against an authentic standard of gentisic acid (Delta Chemical Works, Inc.) in each of the four solvent systems shown in Table 1. In all cases the R_F values of compound *A* were identical with those of gentisic acid. The fluorescence of compound *A* was also observed to be identical with that of gentisic acid, namely, a bright blue, which turned green-white on exposure to ammonia fumes. It was noted that in both cases the greening with ammonia was of a much more transient character than is observed with the chlorogenic acids, the colour reverting to the

Table 1. CHROMATOGRAPHIC COMPARISON OF GENTISIC ACID AND COMPOUND *A* ISOLATED FROM LEAF TISSUE OF *T. cacao* L.

	Gentisic acid *RF*	Compound *A* *RF*
Benzene/acetic acid/water (60 : 70 : 30)	0·28	0·28
20 per cent aqueous potassium chloride	0·55	0·55
*iso*Propyl alcohol/ammonia/water (8 : 1 : 1)	0·71	0·71
Chloroform/acetic acid/water (2 : 1 : 1)	0·30	0·30

original bright blue immediately on removal from the ammonia.

Further confirmation of the identity of compound *A* with gentisic acid was obtained by spraying the chromatogram with an aqueous solution of ammonia (specific gravity 0·910) and immediately examining in ultra-violet light. Under these conditions the gentisic acid spot and that of compound *A* showed a characteristic yellow fluorescence. This change in the colour of the fluorescence from blue to yellow after spraying with ammonia was found to be highly specific for gentisic acid.

The procedure adopted for the routine screening of leaf tissue for gentisic acid was as follows: 2 gm. of fresh, finely shredded leaf tissue were digested with 10 ml. of 20 per cent aqueous hydrochloric acid (v/v) for 20 min. on a boiling water bath. After cooling and filtering, the filtrate was extracted with 2 ml. of diethyl ether and 0·1 ml. of this was applied with a micropipette to Whatman No. 4 chromatography paper, which was formed into a cylinder and developed with benzene/acetic acid/water[3]. The dried chromatograms were then examined in ultra-violet light and the gentisic acid spots located by their blue fluorescence. Confirmation of their identity was obtained by the use of the ammonia spray. Identification was in all cases effected by the use of a marker of authentic gentisic acid.

Representative species of 80 families of Angiosperms were examined by these methods, and positive identifications of gentisic acid were obtained in 73 families. No free gentisic acid was detected in neutral plant extracts; preliminary hydrolysis is essential for the release of the acid from the complex in which it occurs. Studies are in progress on the nature of this complex in tissues of *T. cacao*.

Although gentisic acid was of more frequent occurrence in leaf tissue than caffeic acid, the latter compound is usually present in larger amounts. No correlation was observed between the distribution patterns of gentisic acid and those of other fluorescent phenolic constituents of the leaf extracts.

Although gentisic acid is found in both herbaceous plants and trees, it was notable that in the families included by Hutchinson[6] in the Lignosae, gentisic acid was of more frequent occurrence and tended to be present in larger amounts than was observed in the Herbacae and Monocotylae. It is therefore believed that gentisic acid may be concerned in lignification or in some process associated with it. A similar association has been observed by Bate-Smith in relation to the distribution of leucocyanidins in leaves[7]. Some correlation was also apparent within a family, between the degree of lignification of the genus and the content of gentisic acid present. The relation of gentisic acid to lignification will be discussed in a paper to be published elsewhere.

The widespread occurrence of gentisic acid in plants is also of interest from the point of view of host–parasite relations, since a number of phenolic acids, including protocatechuic acid (3 : 4 dihydroxybenzoic acid), have been shown to confer disease resistance upon certain species of plants. That the content of bound gentisic acid in the surface tissues of the plant may be a factor in the resistance of the plant to fungal attack is, moreover, supported by the observations of Klöpping and van der Kerk[8], who showed that a derivative of gentisic acid from *Populus candicans* possesses highly fungicidal properties *in vitro*.

Rhizobium Needs Magnesium, not Calcium

IN tropical countries there occur abundant examples of legumes that are normally nodulated despite the fact that they grow on acid soils, low in calcium. Observations of some particularly striking examples of this behaviour in the poor 'Wallum' soils of south-east Queensland led to a re-examination of the symbiotic system in the legumes[1]. It was postulated that the tropical legume equipped with cowpea-type *Rhizobium* is adapted to these low-calcium environments because they were the conditions under which the symbiosis evolved, while the clovers and clover type *Rhizobium* are specialized types that have developed calcicole habits. Growth experiments with the bacteria using clays saturated to varying degrees with calcium using McCalla's technique[2] appeared to support the hypothesis, in that strains known to require lime, such as those from lucerne, gave growth in proportion to the degree of calcium saturation of the clay, whereas cowpea-type strains showed relative indifference to the calcium-level. A basic study of the relative calcium requirements of these types was then begun, using a liquid medium in which calcium was supplied in solution, not absorbed on a clay.

To do this a new medium had to be devised. The standard growth medium for *Rhizobium* includes yeast extract which simultaneously supplies nitrogen, growth-factors and minerals, including a significant quantity of calcium. Before a study of calcium requirement could be made it was necessary to prepare a basal medium entirely free from calcium by eliminating yeast extract.

The medium used was constituted as follows:

Disodium hydrogen phosphate	0·45 gm.
Magnesium sulphate	0·1 gm.
Potassium nitrate	0·6 gm.
Ferric chloride	0·01 gm.
Mannitol	10·0 gm.
Thiamin	100 μgm.
Biotin	0·5 μgm.
Distilled water	1,000 gm.

Each ingredient was freed of calcium and all glassware was scrupulously washed with acid. No calcium could be detected by complexometric analysis of the complete medium. The pH of the medium after autoclaving was 7·5 and when 0·02 per cent calcium chloride was added, 6·9.

In this medium 48 strains of *Rhizobium* selected to cover a cross-section of Leguminosae were serially cultured at approximately 14-day intervals for ten generations in comparison with the same medium containing calcium at the normal rate (0·02 per cent calcium chloride). Growth was made in screw-cap tubes containing 10 ml. of medium that was not shaken. All strains made some growth that varied from a trace to 6×10^8/ml. In many cases growth in the series lacking calcium was noticeably superior to that in the parallel series with calcium added. To eliminate the possibility of calcium being obtained from the glass of the culture tubes, transfer of six strains, representing pea, clover, lucerne, cowpea, cassia and acacia, was made from the seventh generation to silica vessels. Serial passage in these vessels to the sixteenth generation was made without loss of vigour.

Mutation, accompanied frequently by loss of infectivity, was high in this medium, but it occurred equally in the series free of calcium and that to which calcium was added.

This experiment showed clearly that *Rhizobium*, whether of clover or cowpea-type, required no calcium for growth. Nevertheless, there remains to be explained the repeated observation that the application of lime to certain soils in which *Rhizobium* will not multiply renders them suitable for growth. One such soil, a krasnozem, was described by Vincent and Waters[3] from Pearce's Creek, near Lismore, New South Wales. Some of this soil was obtained and it was confirmed that, following autoclaving, no multiplication of clover *Rhizobium* was possible in it, but after the addition of calcium hydroxide equivalent to a dressing of 6 tons/acre of lime, populations of $3–5 \times 10^8$/gm. were achieved in seven days. The pH of this soil following autoclaving is approximately 5·0 and it could be argued that the application of lime produced bacterial growth either by eliminating acidity or by supplying needed divalent calcium ions. However, when acidity was eliminated by the hydroxides of sodium, potassium and ammonium, no growth occurred. Furthermore, when equivalent quantities of hydroxides of magnesium or barium were applied, they were as effective as calcium in promoting growth. This eliminated Ca^{2+} as the essential factor but pointed to the need for a divalent cation.

From this point a return was made to the synthetic medium which contained magnesium as its only divalent cation. By several simple experiments it was possible to prove that magnesium was the essential element needed by *Rhizobium.* If the magnesium sulphate in the medium was replaced by sodium sulphate no growth occurred. The addition of calcium, strontium or barium had no effect, but the addition of magnesium resulted in immediate growth.

Apparent growth responses to added calcium on soil or clay are explicable by the position occupied by Mg^{2+} in the lyotropic series. Additions of sodium, potassium or ammonium ions will produce no response since these do not displace magnesium. Additions of divalent calcium or barium ions produce growth response because they displace and render available Mg^{2+} for the bacteria.

Following repeated observations during these experiments that added calcium appeared to be actually inhibitory, presumably by antagonizing the uptake of magnesium, the results were applied immediately to the improvement of growth in agar culture medium, which traditionally contains large additions of calcium carbonate or chloride. By eliminating added calcium compounds and strongly augmenting the amount of magnesium sulphate added, considerable improvement of growth of slow-growing types was obtained.

A full account of these experiments will be published elsewhere.

Field Observations of Midday Closure of Stomata in the Oil Palm, *Elaeis guineensis* Jacq.

During the course of studies on stomatal movement of oil palms under field conditions, some effects of soil moisture on midday closure have been observed. These are of particular interest when examined in the light of the hypothesis of Heath and Orchard[1] on the relationship between leaf temperature and midday stomatal closure.

The technique used was a modification of the infiltration method of Molisch[2], employing a series of *iso*propanol–water mixtures. The results are in good agreement with actual measurements using material fixed by Lloyd's method. All the palms examined were in an area of approximately ¼ acre; they were three years old at the start of this work. Each observation consisted of readings carried out on leaflets from the tip, mid and base of each of six leaves, three on the north and three on the south side of one palm. Each set of three leaves comprised a young, middle-aged and an older, but not senescent, leaf.

Preliminary work in 1956 indicated that midday closure occurred during the latter half of the dry season, which normally extends, with very little or no rain, from November to April, but disappeared with the onset of the rains. During the same period in 1957, midday closure was followed daily. After any appreciable rain, stomatal closure became less severe and remained slight or non-existent until the effect of the rain wore off, and a return to the former state occurred. The extent of closure was correlated with total daily evaporation as measured by a raised tank evaporimeter; after rain a relationship still appeared despite the reduced closure.

To obtain further information on the effect of rain, a comparison was made during the severe dry season of 1958 of the extent of midday closure in two palms, one of which was amply watered. After 33 days the second palm was also watered to show any differences not due to treatment. Air temperature was measured at each observation time

Table 1. THE EFFECT OF WATERING ON MIDDAY CLOSURE OF STOMATA IN THE OIL PALM. PALM 1 WAS WATERED THROUGHOUT AND PALM 2 DURING THE SECOND PERIOD ONLY. THE UNITS OF STOMATAL APERTURE ARE ARBITRARY, SEE FIG. 1

	Period 1		Period 2	
	Difference in		Difference in	
	aperture	temperature	aperture	temperature
Palm 2 (unwatered)	3·39	1·50	—	—
Palm 1 (watered)	±0·14	±0·15	0·03	0·10
Palm 2 (watered)	—	—	±0·07	±0·48

by means of a thermometer 75 cm. above ground-level in the shade of the palm. All the readings were taken between 13h. and 13.30h. local apparent time.

The results are presented in Table 1. There is a significant difference between the extent of midday closure in the two palms which disappears when the second palm is watered. The significant difference in air temperature under the two palms also disappears after watering. Each point in Fig. 1 is a mean of eighteen readings on a single palm plotted against the mean temperature under the palm during the observational period. A difference of 3° C. between the air temperature – leaf temperature relationship for the two treatments would account for the observed differences between the watered and unwatered palms. A significant reduction in the temperature of fully exposed leaflets due to watering was demonstrated, but the instrument used was broken before calibration.

Heath and Orchard propose that midday closure of stomata is a temperature effect operating through the carbon dioxide concentration in the intercellular space. The results presented here confirm their observations on onion and coffee, especially as stomatal closure in the range 30–35° C. is so marked. No leaf temperatures are known, but the effect of watering in reducing air temperature is very clear. The observed lag period between watering and the resulting drop in air temperature indicates that the latter is not due to evaporation at soil-level. Although increasing leaf temperature may cause stomatal closure, it is clear that midday closure of stomata may also be influenced by water strain, whether this operates directly on aperture, with a consequent temperature change due to altered transpiration, or whether, as seems likely in view of Heath and Orchard's work, transpiration affects leaf temperature, which determines stomatal aperture. There would appear to be some justification for regarding midday closure of stomata as a sensitive indication of water stress[3,4].

Light Microscopic and Electron Microscopic Observations on the Dividing Walls of Cells in *Chara* spp.

IN the simple as well as in the higher plants (Thallophyta and Cornophyta) the structure of cell walls exhibits a great variety of characteristics of partly microscopic, partly submicroscopic order of magnitude. These structural peculiarities, which may be characteristic of wider relationships or even of species, are closely connected with the particular functions of the cell. By our investigations, carried out on the cell walls of the genus and species *Chara*, for example, *Chara foetida* A. Br., *Ch. contraria* A. Br., *Ch. hispida* L., *Tolypellopsis stelligera* Mig., *Nitella* sp., *Tolypella intricata* (Trentep.) or Leonhardi, light was cast upon the connexion existing between structure and function.

All material was first treated with dilute hydrochloric acid, and, after thorough washing, with tri-ethanolamine[1], making the dividing walls easily accessible, since the treatment causes the cells to fall apart. Both bulging end-walls of the large internodes were then severed, cut into small pieces and placed on a collodion film. Preparations were shadowed with palladium at a shadowing angle of 15–35°.

In all species examined the end walls of the internodial cells were found to be perforated (Fig. 1). The pores do not arrange themselves regularly; a peculiar system in which mostly two, sometimes three, structural units of different orders of size are desirable (Fig. 2). The largest structural units on the bulging end-wall seem to be regular, polygonal areas produced by the walls of the adhering smaller nodial cells which are in contact. These areas are visible even under the ordinary stereo microscope. We believe these big polygonal areas to be pore fields as they are perforated all over. The distribution of the perforations, however, is irregular; they occur in larger and smaller aggregations, thus forming secondary structural units. These are surrounded in the pore fields by islets consisting of a dense network of cellulose microfibrils. The islets are interconnected by extensions and thus form a lattice delimiting smaller or larger spaces in which a pore cluster is usually contained, the mesh of microfibrils being densely perforated. Less frequently, the lattice encloses regular, triangular or quadrangular spaces and exhibits thinner strands running diagonally, formed by still smaller pore clusters aggregated within the larger ones and thus representing structural units of the third grade (Fig. 2).

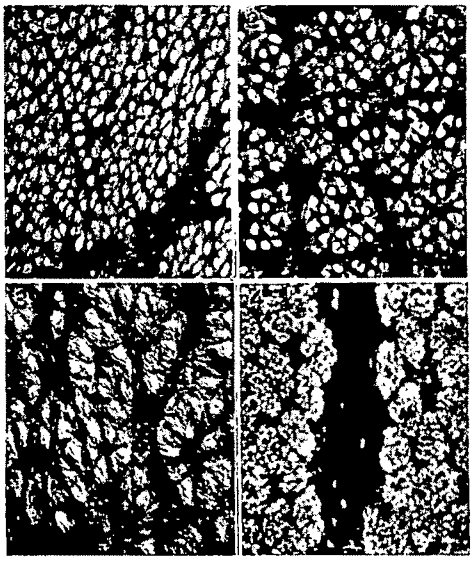

Fig. 1. Detail from the end-wall of the axial internode of *Chara contraria*. (Electron micrograph, × 3,400)

Fig. 2. Pore clusters in the end-wall of the axial internode of *Chara contraria*. (Electron micrograph, × 4,000)

Fig. 3. Detail from the end-wall of the axial internode of *Chara hispida*. (Electron micrograph, × 4,000)

Fig. 4. Detail from the end-wall of the axial internode of *Chara contraria* in the phase contrast microscope. (× 750)

The average diameter of the pores is 400 mμ, their shape is a more or less distorted circle, surrounded by a densely woven texture of cellulose microfibrils. At times the opposite apertures of the pores do not coincide, the pores presumably being oblique. The various species show differences as to the form, dimensions and arrangement of the pores (Fig. 3).

The islets and the perforations mentioned above being within the range of the light microscope, their microscopic examination was also undertaken. Under the phase-contrast microscope not only the network surrounding the pore clusters but also the larger pores themselves were easily observable (Fig. 4).

With the help of easily recognizable islets, identical spots could sometimes be photographed in the light microscope and in the electron microscope. It was proved by further examinations that the walls communicating with the end-wall of the axial internode of the smaller nodial cells, as well as the contiguous walls of the internodial and nodial cortex cells were also perforated. The side-walls of the axial internode and of the internodial cortex cells, however, do not have a similar porous structure[2].

It may be assumed with certainty that the pores in question are the crossing points of the cytoplasmic threads connecting the contiguous cells, the so-called plasmodesmata. These are responsible for the unity in the physiological functioning of the alga and are analogous to the porous structure recognized in the cell wall, more precisely in the pits of the cell wall of higher plants[3-6]. It is due probably to the extraordinary size of the cells that the pores of various *Chara* sp. have dimensions well within the range of the light microscope. The pore fields are of the order of mm.[2] and the network probably serves to strengthen the comparatively large, but exceedingly thin, porous membrane.

Full details of this work will be published in the near future. We wish to thank Mrs. T. Tóth for the excellent technical help she has given.

Effect of Storage Conditions on the Incidence of *Gloeosporium* Rots of Apple Fruits

SAMPLES of Cox's Orange Pippin obtained from various parts of south-east England were held in cold (37° F.) and in gas (39° F., 3 per cent oxygen and 5 per cent carbon dioxide) storage for periods of approximately 3½ months and 4½ months respectively. On removal from storage, the samples were examined for rots caused by *Gloeosporium* spp., but owing to lack of time the causal species on each rot was not identified. It was noted during 1955–56 and 1957–58 and, to less marked extent, in 1956–57 also, that in certain samples the percentage of apples recorded as damaged by these rots was less after gas storage than after cold storage, despite the higher temperature and longer period of storage, whereas with other samples the converse occurred.

A preliminary examination of seventeen samples after gas storage in 1957–58 indicated that the different behaviour of samples in this respect might be caused by a difference in the predominating species of *Gloeosporium*. Larger sub-samples, of up to 25 apples, were therefore taken from four samples that showed decreased rotting in gas store and from four that showed increased rotting, each sample being from a distinct orchard. The fungus causing each rot was identified by its spores, apples with non-sporing rots being kept at room temperature in polyethylene bags until as many of the rots as possible had been identified. The results are presented in Table 1.

G. album usually develops in storage more slowly than *G. perennans*, and this might make it more susceptible to the concentrations of carbon dioxide and oxygen reached some days after the store is

Table 1. ROTTING OF SAMPLES IN COLD AND IN GAS STORE, IN RELATION TO PERCENTAGE OF ROTS DUE TO *Gloeosporium album*

Origin of sample	Percentage of apples infected with *Gloeosporium* spp. Cold store	Gas store	No. of rots due to: *G. perennans*	*G. album*	Percentage of rots due to *G. album*
Eynsford	76	35	25	49	64

Canterbury	27	41	84	4	5
Burlingham	29	48	98	7	7
Marden	12	32	70	—	—

closed. Alternatively, its late development in store may be linked with an advanced stage of maturity of the apple and therefore make it more likely to be affected by a treatment such as gas storage that delays maturity.

Quite apart from the potential economic value of this finding, if confirmed, the results suggest that there are important differences in the biology and mode of parasitism of these two species of *Gloeosporium*.

Terpene Formation in Pine from Mevalonic Acid

Recent studies have demonstrated that mevalonic acid is a key intermediate in the biosynthesis of animal sterols[1]. Studies of the origin of triterpenes and carotenoids in soya bean and fungi indicate that these compounds may also be formed from acetate through mevalonic acid[2]. Although the incorporation of atmospheric carbon dioxide into pine terpenes has been demonstrated[3], studies on the nature of the pathway by which these compounds originate have not been reported. In the present work, seedlings of *Pinus attenuata* were found to incorporate acetate-2-^{14}C and mevalonic acid-2-^{14}C into the monoterpenes. The turpentine of this pine is 98 per cent α-pinene[4].

Shoot tips were cut from actively growing 2-year-old seedlings of *P. attenuata*. These shoot tips (about 3 gm.) were placed in cone-shaped vials containing 1 ml. of the radioactive substrate in 0·01 *M* potassium phosphate buffer, *p*H 5·9. The vials, with the base of the shoot tips immersed, were sealed with 'Parafilm' wax paper to prevent evaporation. The tops were then exposed to a 100-watt incandescent lamp and air was blown across them to induce rapid transpiration and uptake of the substrate. Sufficient water was added to the vials to keep the stem bases submerged during the 8 hr. they were allowed to metabolize the absorbed solutions. On removal the shoots were frozen in liquid nitrogen, wrapped in aluminium foil and stored at −10° C. until extracted. Extraction was by homogenization in ethyl ether with mortar, pestle and sand. The samples were extracted until radioactivity was absent from the ether extract. Finally, the homogenized tissue was shaken in a closed Erlenmeyer flask on a mechanical shaker for 3 hr. with four changes of ether. This ether was combined with the earlier extract and the combined volume (about 200 ml.) was reduced to 20 ml. by distillation at 38° C. This concentrate was passed through a column (70 mm. high, 15 mm. diameter) packed with basic alumina oxide (Woelm) and 'Darco' decolorizing charcoal. The column was washed with approximately 100 ml. of ether yielding a colourless eluant containing a minimum of acid residue. The ether eluant was concentrated by distillation to 0·5 ml. and pure α-pinene (0·2 ml.) was added to the ether concentrate. The α-pinene was then separated from a portion of this mixture by gas-liquid-partition chromatography with helium as the mobile phase and 'Carbowax' 1540 on diatomaceous earth as the stationary phase. The α-pinene, fraction *A*, was collected at 120° C. (Fig. 1). The column temperature was then increased to 190° C. while helium was permitted to flow through for 30 min. to flush the column. Fraction *A* was then resubjected to chromatography at 120° C. and fraction *B* isolated. Fraction *B* was again chromatographed and separated into two fractions, *C* and *D*. The infra-red spectra of the material isolated in fractions *B*, *C* and *D* were identical with that of pure α-pinene; the specific activities of the pinene in each of these fractions was found to be constant (Fig. 1).

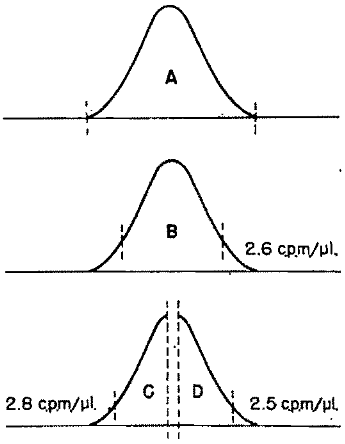

Fig. 1. Specific activity in carbon-14 of α-pinene fractions characterized by gas chromatography. α-Pinene was extracted in ethyl ether from shoot tips of *Pinus attenuata* incubated for 8 hr. with $8{\cdot}8 \times 10^6$ c.p.m. mevalonic acid-2-^{14}C. Counted by liquid scintillation in 0·5 per cent 2,5-diphenyloxazole in toluene (ref. 6). Specific activity expressed as c.p.m./µl. of α-pinene

The nitrosochloride was then prepared from another portion of the final ether extract containing carrier α-pinene. The specific activities present in the crystals isolated after three and four recrystallizations are given in Table 1. From this evidence we may conclude that the carbon-14 derived from mevalonic acid is incorporated into α-pinene in pine. Complete details of this study will be published elsewhere.

The amount of radioactivity recovered in the α-pinene of the shoot rips was approximately 0·02 per cent after 8 hr. incubation. When slices of *P. attenuata* were incubated for 2 hr. with mevalonic acid-2-^{14}C, 0·5 per cent of the activity was recovered in α-pinene. In similar experiments with acetate-2-^{14}C, approximately 0·01 per cent was incorporated in the α-pinene fraction of whole shoot tips. However, acetate can be metabolized many ways in pine tissues[5]. It would therefore be erroneous to conclude from these preliminary studies with intact tissues that mevalonic acid is incorporated in preference to acetate.

I wish to thank Drs. N. T. Mirov, P. K. Stumpf and R. Lemmon of the University of California, Berkeley, for the use of laboratory facilities and for constant encouragement in these studies; appreciation is also expressed to the Fundamental Research Group at Merck and Co., Rahway, New Jersey, for

Effect of Simulated Field Deposits of Gamma-BHC and Dieldrin on Susceptible, Hybrid and Resistant Strains of *Anopheles gambiae*, Giles

SINCE the first recognition of resistance to dieldrin in *Anopheles gambiae* in Northern Nigeria[1], laboratory studies have shown the degree of resistance to this insecticide to be of a very high order—some 800 times—and that cross-resistance to gamma-BHC is involved, though of a comparatively low order—some 30 times[2]. This type of resistance has further been shown to be monofactorially inherited, the hybrid being intermediate in its resistance—some 30 times to dieldrin and only 8 times to gamma-BHC[3]. The resistant strain remains susceptible to DDT, though there has always been some doubt as to the efficiency of this insecticide in controlling malaria transmitted by *A. gambiae* because of the irritant effect of the insecticide and the consequent low mortalities achieved[4].

A series of observations has now been made to determine the effect of simulated field applications of commercial formulations of gamma-BHC and dieldrin on susceptible, hybrid and resistant strains of *A. gambiae* derived from colonies maintained at the Ross Institute of Tropical Hygiene, London. The main purpose of the experiment was to see if these applications would produce any mortality among the hybrid and resistant mosquitoes and, if so, for how long. In addition, the persistence of the two insecticides at similar dosages on sorptive mud blocks has been compared.

Blocks of a highly sorptive mud from Babati in Tanganyika, 3 in. in diameter and ½ in. thick, were kindly prepared and sprayed with insecticide by A. B. Hadaway and F. Barlow of the Colonial Insecticide Research Unit, Porton Down.

Gamma-BHC was applied at 25 and 50 mgm./ft.^{2} and dieldrin at 50 mgm./ft.^{2}, using in both cases 50 per cent dispersible powders. The test method used was for the most part similar to that employed by Hadaway[5]. A 'Perspex' exposure chamber was placed vertically against the treated surface of each mud block and approximately 20 unfed adult mosquitoes were transferred to the chamber from a collecting tube. The experiments were conducted in a constant temperature and humidity room (80° F., 75 per cent relative humidity). The mud blocks were stored between tests under these same conditions and the same blocks used for tests at successive dates. The exposure period of mosquitoes to the blocks ranged from 30 min. to 7 hr. according to the age of the residue. After exposure the mosquitoes were lightly anæsthetized with chloroform vapour and removed to net-covered paper cups where they were fed with 10 per cent glucose solution and held for 24 hr., at the end of which time the mortality was determined. Both male and female mosquitoes were exposed, and though in general the former showed a higher mortality than the latter, the combined mortality has been given in the final rendering of the results. As a control to the experiment mosquitoes were similarly exposed to an untreated mud block.

The results of these exposures up to 8 weeks after treatment of the mud blocks are given in Table 1. It can be seen that all three treatments give very high mortalities with susceptible *A. gambiae* throughout the two-month period when an exposure of one half-hour is made. Such high mortalities have in fact continued with both gamma-BHC and dieldrin at 50 mgm./ft.^{2} to the time of writing (13 weeks) with the same exposure time, though the lower dosage of gamma-BHC now only gives a mortality of about 40 per cent.

Table 1. PERCENTAGE MORTALITIES AMONG MALE AND UNFED FEMALE, SUSCEPTIBLE, HYBRID AND RESISTANT *A. gambiae* EXPOSED FOR VARYING TIMES TO RESIDUES OF GAMMA-BHC AND DIELDRIN OF VARYING AGES

Strain	Insecticide (mgm./ft.^{2})	Exposure period (hr.)	Age of residue				
			1 day	1½–2 weeks	3 weeks	6 weeks	8 weeks
Susceptible	Gamma-BHC 25	½	100	93	—	89	95
	Gamma-BHC 50	½	100	100	—	100	100

* Over-anæsthetized.

Fresh deposits of gamma-BHC gave complete mortalities of hybrid *A. gambiae* after exposure of ½ hr., and the higher dosage of gamma-BHC continued to give this mortality with the same exposure time up to 2 weeks after treatment. Dieldrin in the fresh state also killed most hybrids though exposure of 1 hr. was necessary. With ageing of the deposits longer and longer exposures were necessary to produce significant kills. After 8 weeks, 4 hr. exposure was necessary to kill all hybrids on the lower dosage of gamma-BHC and 7 hr. exposure to dieldrin only resulted in a third of the hybrids dying. The higher dosage of gamma-BHC continued to produce high mortality at much shorter exposure times.

The resistant *A. gambiae*, as might be expected, proved much more difficult to kill. In the fresh state both dosages of gamma-BHC gave high kills at quite short exposure times, but after 8 weeks 7 hr. exposure was necessary on the higher dosage to give a high mortality rate. Dieldrin never at any time gave satisfactory kills at the exposures given.

These results indicate that a persistent kill of hybrid *A. gambiae* by gamma-BHC with a consequent delay in the appearance of the resistant strain may be expected where this insecticide is used. However, it should be pointed out that this method of exposure in a small confined space may give rise to artificially high mortalities because of the accumulation of insecticide in the vapour state, a condition less likely to arise in Nature. It should also be pointed out that a resistant strain of the species did arise in Kano, Nigeria, as a result of the use of gamma-BHC, if not over a short period, then certainly over a comparatively small area[6].

The current conviction that two types of resistance occur in anopheline mosquitoes, one to DDT and the other to the dieldrin–BHC group of insecticides, and that the possibility of the two types occurring in one and the same population of the same species is very remote, has led to a consideration of the possible use of mixtures of insecticides for preventing the appearance of resistant strains. The choice would of necessity at present lie between DDT and gamma-BHC and DDT and dieldrin. In view of the marked irritant effect of DDT the chances of a mosquito escaping unharmed from a mixture would be greater where dieldrin is involved, owing to the lower toxicity of this insecticide compared with gamma-BHC. The results of the present experiments would further favour the choice of gamma-BHC in the mixture and indicate that a higher dosage than the customary 25 mgm./ft.^{2} will produce a persistence more in line with that of dieldrin at 50 mgm./ft.^{2}.

Radioassay of Carbon-14 in Aqueous Solutions using a Liquid Scintillation Spectrometer

MOST compounds of biochemical interest have only limited solubility in organic solvents, and the useful fluors described to date have only limited solubility in aqueous solutions. This basic incompatibility has limited the application of liquid scintillation counting methods in many biochemical tracer studies. The method described below permits direct counting of aqueous solutions (or alcoholic solutions). In addition, it permits quantitative recovery of the sample in its original form for further analyses, often an important advantage when the quantity of sample available is limited.

The method is based on the principle of using a two-phase system: a solid phase consisting of a multitude of small, clear particles (plastic or glass) into which a fluor has been incorporated and a liquid phase containing the radioactive mixture to be assayed.

Preliminary experiments were carried out using small cylindrical filaments of 'Pilot Scintillator *B*' 3·2 cm. long and 0·043 cm. in diameter, which had been originally designed for use by physicists in particle-tracking experiments. A bundle of these filaments was packed tightly into a section of glass tubing (0·8 cm. × 4·4 cm.) and aliquots of a standard solution of aqueous sodium carbonate-^{14}C (National Bureau of Standards reference source), containing 1,280 disintegrations/sec./ml., were allowed to seep into the bundle by capillary action. The tube was placed upright in a Wheaton Glass Company counting vial and counted in a Packard 'Tricarb' scintillation spectrometer. As shown in Fig. 1 (inset), the corrected count-rate increased linearly with increasing volume of sample. The efficiency was 29 per cent. When the vial was allowed to stand in the refrigerated counting chamber for several hours, the count-rate was observed to rise markedly as the solution froze. Thawing returned the count-rate to the original value. Quick freezing, on the other hand, did not change the count-rate significantly. This rise in count-rate on slow freezing is attributable to separation of the solute phase so as to concentrate it in the vicinity of the beads. For routine use

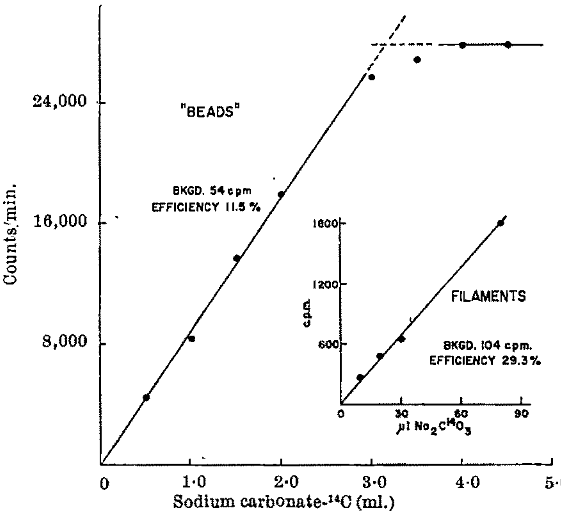

Fig. 1

aqueous samples should be counted above their freezing point. Because the filaments were very tightly packed, it was possible to rinse out the labelled solution without disturbing their packing, and, after rinsing with alcohol and drying, re-use them. A limitation of this method is that the geometry of the system makes it difficult to add an internal standard and be certain of complete mixing. Quenching correction could be determined by adding internal standard to a second aliquot and counting it separately. The hand-packing procedure is tedious and impractical, but if uniformly packed vials of filaments become available commercially, the use of this system might be feasible. A more practical system for routine use would employ uniform spherical beads of plastic scintillator.

The feasibility of the latter approach was explored by cutting the cylindrical filament into very short (1–2 mm.) segments. 4·4 gm. of these 'beads' (approximately 7·7 ml. in volume) were placed in a counting vial and successive aliquots of the aqueous radioactive sodium carbonate standard were added. The count-rate increased in proportion to sample size up to about 3·0 ml. (Fig. 1) and the absolute efficiency was 11·5 per cent. The count-rate then dropped off and reached a plateau as would be expected. With an excess of liquid sample added to a measured quantity of scintillator beads, the observed count-rate is directly proportional to the specific radioactivity of the solution in counts/min./ml. independent of the exact volume added, since the interstices are then completely filled with the labelled solution. This is quite analogous to the counting of solid samples at infinite thickness. It should be pointed out that the density of the plastic used here (1·02) was such that the 'beads' did not pack solidly and this accounts for some of the deviation from linearity seen in Fig. 1. In addition, of course, the simulated 'beads' cut by hand for this purpose were not uniform and did not pack homogeneously. Still, the large number of particles used appears to have resulted in reasonably reproducible average packing. Repeated counts on an aqueous solution of l-lysine-^{14}C, shaken up between counts, were 1,838, 1,773, 1,728 and 1,755 counts/min. Addition of water reduced the observed count-rate in proportion to the dilution of the original radioactive solution, demonstrating completeness of mixing and further validating the direct relation between count-rate and specific radioactivity in counts/min./ml.

Finally, it was shown that a correction for quenching can be accurately made in the usual way by adding a known amount of radioactivity in a minute volume, mixing and recording the increment in count-rate. If a constant quantity of 'beads' is used and an excess of radioactive solution, this internal standard correction also corrects for volume and makes it unnecessary to measure accurately the volume of solution being assayed, provided it completely covers the 'beads'.

The plastic scintillator used in this work, 'Pilot Scintillator B', containing diphenylstilbene, was supplied by Pilot Chemicals, Inc., Watertown, Mass., and I thank Mr. Mark Hyman, of that firm, for providing this material. Uniform short cylindrical segments will soon become available for distribution.

Stability of Metal Complexes with Salicylic Acid and Related Substances

SALICYLIC acid and its derivatives can form chelate compounds with metal ions. Unfortunately, the paucity of data on stability constants in aqueous solutions[1] has prevented assessment of the biological significance of this property in the outstanding anti-rheumatic and anti-fungal actions of these substances, as well as in their toxic action to man in higher dosage.

Stability constants are now reported for the chelation of some cations with salicylic acid and some related substances. In near-neutral solutions the carboxyl-group of salicylic acid is almost completely ionized, so that simple complex formation with a metal ion would not lead to the considerable liberation of hydrogen ions found, and hence the metal ion must displace the hydrogen ion from the phenolic group. The resulting change in the pH of the solution enabled Bjerrum's potentiometric method[2] to be used to obtain the stability constants of the divalent cations. Where permissible, appropriate mathematical simplifications of the calculations were made[3]. In many instances hydrolysis or precipitation prevented direct determination of log K_2, so for all except cupric and ferric ion, log K_2 was obtained by subtracting log K_1 from log K_1K_2 (found at $\bar{n} = 1$). Constants for ferric complexes were calculated from the dependence on pH of oxidation-reduction potentials[4]. All solutions were titrated under nitrogen. Sodium perchlorate or perchloric acid was added to maintain an ionic strength of 0·15, thus approximating isotonicity with blood. All metals were added as perchlorates except cadmium (sulphate) and manganese (chloride). For all ligands except salicylaldehyde the ionization constant of the phenolic group was measured spectrophotometrically either in sodium hydroxide solution, using known activity coefficients[5] to calculate hydrogen ion concentrations, or in buffer solutions of known pH. All other ionization constants were determined by potentiometric titration.

Reliable ionization constants could not be obtained for salicylamide (which hydrolysed rapidly in alkaline solutions) or for the catechol anion (which oxidized very readily in air). The rough estimate of $pK_2 = 13$ for catechol was based on potentiometric titration under nitrogen.

The present value of log K_1 for the copper salicylic acid complex confirms Babko's[8] figure, but log K_2 is much higher than previously reported[8]. The stability constants of the ferric complexes of salicylic and sulphosalicylic acids are consistent with published[9] data and are much greater than for the corresponding copper complexes.

Stabilities of the complexes of the divalent metals conform to the Irving–Williams series[10]: Mn $<$ Fe $<$ Co $<$ Ni $<$ Cu $>$ Zn. The rather small increment in passing from manganese to nickel, with a greater increase from nickel to copper, is similar to results for other ligands in which bonding of the metal occurs with two oxygen atoms[11].

Table 1 shows that, of the o-substituted phenols examined, both salicylic and 5-sulphosalicylic acid are powerful chelating agents. However, to compare their chelating abilities under biological conditions with those of other ligands it is necessary to calculate from these results the distribution of selected cations between equal ligand concentrations at the same pH. This has been done in Table 2 for approximately neutral solutions of salicylic acid, sulpho-

Determination of Strychnine in Nux Vomica by Paper Chromatography

MOST methods used for the estimation of strychnine in nux vomica lead to gross inaccuracies due to brucine interference. Even oxidation of brucine with nitric acid under optimal condition (5 min. at 60° C.) leads to errors due to partial destruction of strychnine[1]. Gravimetric estimations also require amounts greater than 0·1 gm. in the sample[1].

Paper chromatography has also been applied, but most of the methods have difficulty in separating brucine from strychnine. Dušinský and Tyllová[2] have overcome this difficulty by using nitric acid to oxidize brucine to *o*-brucichinone. This method probably suffers from errors outlined by de la Vega and Del Pozo[1].

These can be obviated by using a simplified method. The aqueous sample was made alkaline with sodium hydroxide and the alkaloids were extracted with chloroform. The chloroform was then evaporated in a water-bath. The resulting alkaloids were dissolved in a measured volume of chloroform and aliquots of this extract, containing 60–20 γ strychnine, were spotted on to Whatman No. 1 chromatography paper and developed overnight with *n*-butanol/*n*-propanol/0·05 *N* hydrochloric acid (1 : 2 : 1 v/v) at 20° C. by the ascending technique. The paper was dried and photographed in the ultra-violet to reveal the spots. The paper was then cut and eluted with water. The strychnine hydrochloride was estimated using a Beckman spectrophotometer model *DU* at $\lambda_{max.}$ 255 mμ [3].

Isolation of Piperonylic Acid from *Ocotea pretiosa*

As part of work on the chemical constituents of Brazilian Lauraceae[1], we examined the benzene extractives (2·4 per cent) of the wood of *Ocotea pretiosa* (Nees) Mez, the sassafras tree of the State of Santa Catarina producing essential oil (chiefly safrole). Through extraction with aqueous bicarbonate solution a solid (comprising 0·03 per cent of the wood) was isolated and purified by crystallization from chloroform and vacuum sublimation. White crystals were obtained, melting point 227–29° C. (Kofler block). Determination of the melting point of a mixture and infra-red spectral comparison with an authentic sample established its identity with piperonylic acid.

Piperonylic acid is, apparently, quite rare in Nature. Its known occurrence is restricted to the plant family Lauraceae, where traces of it have been found accompanying relatively much larger amounts of substances containing the piperonyl moiety. Only once before[2] has it been isolated by solvent extraction from a natural source, the coto barks, where it occurs along with 6-piperonyl-α-pyrone (*Aniba coto* Kostermans) and accompanying 6-piperonyl-α-pyrone, 2,4-dimethoxy-6-hydroxy-3′,4′-methylenedioxybenzo-

Inside information - on supplies to your laboratory

The new Loughborough catalogue, 'Laboratory Equipment' has three sections :

Interchangeable Laboratory Glassware.
Plastics Laboratory Equipment.
General Laboratory Equipment.

"Hey! have you seen the latest Loughborough Glass catalogue ? "
"Yes — don't interrupt! — I'm just reading it."
"Mind if I look too ? — Hm — yes — not bad."

"Good idea bringing the old 'Interchangeable' and 'General' catalogues under the same cover — there's a lot of new stuff too."

"Yes but what about this section on Plastics Laboratory Equipment ? Some really good ideas here. You know, there's something in this business of plastics for laboratory ware — it's so tough, resistant and versatile — just look at this, for instance — and this . . . "

"Do you mind! — this is *my* copy. You only have to ask, you know, and these Loughborough people will send you a copy like a shot, *and* put your name on their mailing list for future 'inside information'."

"Of course! I've been meaning to — I'll do it now."

Shape of Spot and Rate of Sorption in Paper Chromatography

Chromatography is characterized by a dynamic distribution of a substance between a stationary phase and a mobile phase in which diffusion occurs[1]. In the case of a linear sorption isotherm, the exchange reaction between the two phases may be considered to be of the first order.

In spite of this, most theories of chromatography are based on simple equilibrium considerations and diffusion is frequently neglected[1-3]. Although diffusion is considered in a series of papers on sorption-rates by Wicke[4], he considers sorption fronts only and does not apply his analysis to the exchange reaction which occurs in chromatography. In recent papers[5] Giddings has considered the exchange reaction using a discrete model of chromatography, thereby obtaining results similar to ours.

In the present communication we show for a simplified model how the diffusion in the mobile phase and the dynamic character of the exchange process may be taken into account. The random exchanges of a molecule between the adsorbed and the desorbed states interact with the bulk flow in the mobile phase to create a random motion, which is observed macroscopically as an additional diffusion superimposed on the ordinary diffusion in the mobile phase. We shall show that this increase in diffusion in the direction of the flow in the mobile phase may be derived from the general differential equations for the concentrations of adsorbed and desorbed molecules. These equations have been discussed by us in connexion with electrodiffusion[6].

In paper chromatography the spot is often observed to be elongated in the direction of the flow of the developer[1,7]. This fact has not yet to our knowledge been satisfactorily explained. We shall, however, show that for the simple model considered here and in the absence of secondary reactions or transformations on the paper, this may be explained as a consequence of the interaction between the exchange process and the bulk flow. By comparing the dimensions of the spot in the direction of developer flow and at right angles to that direction, it is possible to estimate the values of the rate constants for adsorption and desorption.

Consider a thin layer of a fluid phase streaming in the x-direction with uniform velocity v over a two-dimensional fixed phase. The substance which takes part in the chromatographic process is introduced at zero time at the point $x = y = 0$. We shall assume the initial distribution to be given by a δ-function with the whole amount of substance in the fixed phase. It will further be assumed that we can neglect diffusion in the fixed phase.

If the concentrations of the substance considered are c_1 in the mobile phase and c_2 in the fixed phase, the behaviour of the system, taking into account only motion in the x-direction, may be described by the partial differential equations:

$$\frac{\partial c_1}{\partial t} = D\frac{\partial^2 c_1}{\partial x^2} - v\frac{\partial c_1}{\partial x} - k_1 c_1 + k_2 c_2 \qquad (1)$$

$$\frac{\partial c_2}{\partial t} = - k_2 c_2 + k_1 c_1 \qquad (2)$$

D is the simple diffusion coefficient, whereas k_1 and k_2 represent the rates of adsorption and desorption, respectively, with respect to the fixed phase and include all effects due to the boundary layer and to diffusion at right angles to the fixed surface. A discussion of the relation between actual reaction-rates at the surface and diffusion towards the surface has been given by Prigogine[8].

These equations are solved by Fourier transforms with respect to x, retaining in the solution of the resulting ordinary differential equations only terms up to the first order in Dz^2, where z is the new independent variable. We obtain:

$$c_1 = \frac{k_2}{2(k_1 + k_2)\sqrt{\pi \mathbf{D}_x t}}\left(\exp - \frac{\xi^2}{4\mathbf{D}_x t}\right)[1 + f_1(\xi,t)] \qquad (3)$$

$$c_2 = \frac{k_1}{2(k_1 + k_2)\sqrt{\pi \mathbf{D}_x t}}\left(\exp - \frac{\xi^2}{4\mathbf{D}_x t}\right)[1 + f_2(\xi,t)] \qquad (4)$$

where $\mathbf{D}_x$ represents the 'effective diffusion coefficient' in the x-direction given by:

$$\mathbf{D}_x = \frac{Dk_2}{k_1 + k_2} + \frac{k_1 k_2}{(k_1 + k_2)^3}v^2 \qquad (5)$$

and ξ is a distance co-ordinate the origin of which is moving along with the maximum of concentration, that is,

$$\xi = x - \frac{k_2 v}{k_1 + k_2}t \qquad (6)$$

The functions $f(\xi,t)$ contain rapidly decaying transient terms.

After a time sufficiently long for the transient terms to become insignificant, the chromatography process in the simplified model considered may thus be described by an ordinary diffusion equation with diffusion constant $\mathbf{D}_x$ and distance co-ordinate ξ.

Following the same procedure as before, it is readily shown that the concentration distribution in the y-direction is given by:

$$c_i = \frac{k_i}{2(k_1 + k_2)\sqrt{\pi \mathbf{D}_y t}}\left(\exp - \frac{y^2}{4\mathbf{D}_y t}\right) \qquad (7)$$

where

$$\mathbf{D}_y = \frac{Dk_2}{k_1 + k_2} \tag{8}$$

The solution of the two-dimensional form in x and y of equations 1 and 2 is the product of the solutions 3 and 7, and it follows that the contour of the spot corresponding to a given concentration is an ellipse the principal axes of which, a_x and a_y, are proportional to the square roots of the effective diffusion coefficients in the x- and y-directions, that is :

$$\frac{a_x}{a_y} = \sqrt{\frac{\mathbf{D}_x}{\mathbf{D}_y}} \approx 1 + \frac{k_1 v^2}{2D(k_1 + k_2)^2} \tag{9}$$

The present theory thus provides not only a value for the rate of advancement of the spot but also gives an explanation for its shape. Furthermore, by comparing the two axes of the elliptical spot at different velocities, it is possible to deduce the values of the rate constants k_1 and k_2 for adsorption and desorption. More accurate values of the rate constants k_1 and k_2 may be obtained by measuring the rate of spreading of a spot or band at different velocities of developer flow.

We thank Prof. I. Prigogine for his interest in this work, which has been made possible by the support and sponsorship of the Air Research and Development Command, United States Air Force, through its European Office. One of us (W. G. K.) is indebted to the Commonwealth Scientific and Industrial Research Organization, Australia, for an overseas studentship, and the other (T. A. B.) to the University of Copenhagen for a grant in aid.

Migration-elution of Zones in an Electrophoresis Column

So far the preparation of electrophoretically defined fractions by means of zone electrophoresis in powder columns has been performed in two separate steps. Electrophoresis has been succeeded by displacement of the solution in the column[1 2] or the entire contents of the column have been removed from the tube and cut in segments from which the substance has been recovered by washing[3,4]. Both methods obviously suffer from a number of drawbacks. The latter technique is rather time-consuming and is especially complicated when applied on a large scale (100-ml. sample or more). The former method is simple in operation but its main disadvantage is its dependence on the filtering properties of the powder. As Kunkel[4] has pointed out, the displacement of zones after electrophoresis will to some extent impair the separation already achieved at the end of the first step.

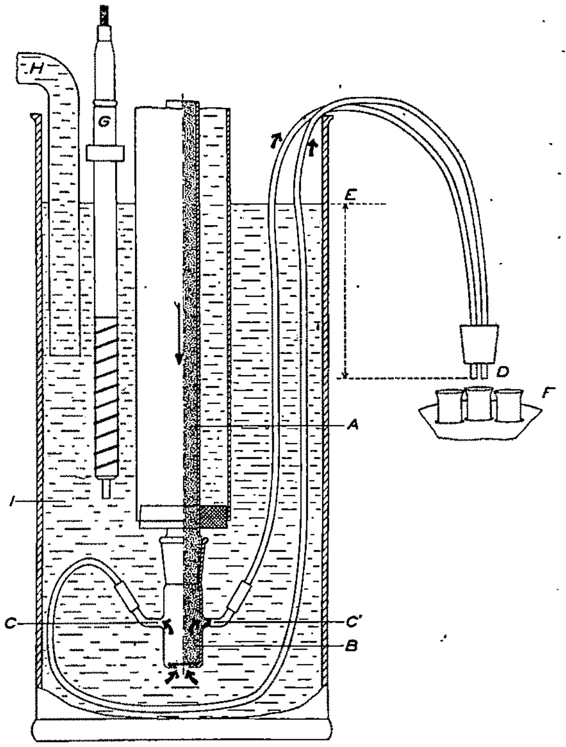

Fig. 1. Arrangement for continuous removal of zones during electrophoresis (see refs. 5 and 6). The electrophoresis column *A* is filled with powder surrounded by a cooling jacket and provided with the short column *B*. In addition to the column the electrode *G* and a tube *H* is dipped into the electrode vessel *I*. The tube *H* connects the buffer in *I* with a buffer reservoir for keeping the liquid-level *E* constant

We have found it possible to remove continuously the zones at a fixed level in the column by a buffer flow operating in the direction opposite to the electrophoretic migration. A simple arrangement for the utilization of this principle is shown in Fig. 1. In column *A* the zones move electrophoretically towards the bottom and pass a thick filter paper and a platinium net at the end of *A*. After entering a second short column *B* attached to *A* they meet a counter current of buffer solution. This causes the displacement of the zones through the side arms *C* and *C'* and through two capillaries the other ends of which are placed above a tube in a fraction collector *F*. The counter flow of liquid, which is determined by the hydrostatic pressure head *ED*, should be adjusted so that it safely exceeds the electrophoretic migration velocity of the fastest moving zone. Too high a rate of flow should be avoided, of course, since it will unduly dilute the samples to be collected. For obvious reasons the liquid flow should be decreased with time if the electric field-strength is kept constant during the experiment. A continuous decrease of the rate of flow proportional to the time should be most convenient.

The side arms may be placed directly at the lower end of *A* or at the upper end of the tube if electrophoretic migration upwards is preferred. However, the arrangement in Fig. 1 makes it possible to fill the tubes *A* and *B* with different anticonvection media. This opens up new fields of application of column electrophoresis. If the tube *A* is filled with a material

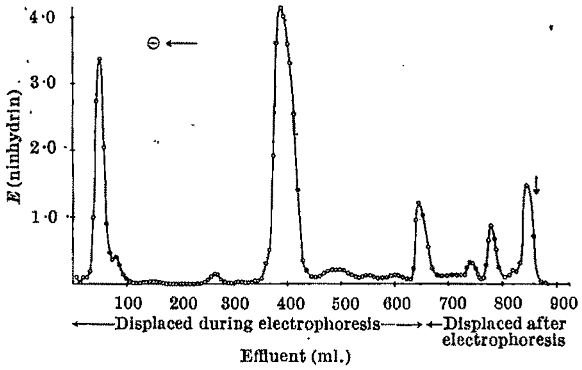

Fig. 2. Electropherogram of a mixture of basic peptides of the posterior lobe of pig pituitary (starting zone marked by the arrow). The sample had been obtained after a number of purification steps, including extraction, precipitation, ion-exchange chromatography and counter-current distribution. The large peak at the effluent volume of 400 ml. corresponds to lysine-vasopressin. When about 640 ml. of effluent had been collected during the electrophoretic run, the electrophoresis was stopped and the substances still remaining in the column were displaced by fresh buffer solution

of good stabilization but poor filtering properties such as a plastic powder or even a gel and if *B* is filled with powder suspension, a continuous displacement of zones should be possible with the retention of a high degree of resolution. Such experiments are now in progress.

Fig. 2 illustrates the result of an application of the method. The experimental details were as follows: 200 mgm. of a mixture of basic peptides from the posterior lobe of pig pituitaries were dissolved in 1 ml. of 0·3 *M* pyridinium acetate solution (*p*H 4·9) containing 0·5 per cent phenol as a preservative. The solution was applied at the top of a cylindrical column 71 cm. long, 2 cm. wide, cooled externally and containing the same buffer stabilized by cellulose powder[7]. The solution was allowed to sink into the column by the force of gravity and was displaced by fresh buffer to a position 2 cm. below the upper surface. The small column *B* was now attached to the lower end of *A* (Fig. 1) and immersed in the buffer of electrode vessel *I*. Liquid connexion with the other electrode vessel was established as described elsewhere[5,6] and the free ends of the capillaries *D* were placed over the fraction collector. The column *A* was cooled by circulating tap water of +10° C. through the cooling jacket. A potential difference of 480 V. between the electrodes resulted in a current of 40 m.amp. After 22 hr. the elution through the capillaries was started while continuing the electrophoresis. One 5·9-ml. fraction was collected every half hour. After 71 fractions had been collected the pressure head *ED* was decreased to yield 3·6 ml./hr. and one fraction was collected hourly. From fractions 115 to 142, 2·3 ml. of eluent an hour was removed from the column. The electrophoresis was now stopped and the material remaining on the column displaced by fresh buffer at a rate of 5·3 ml./hr. One fraction was collected every 5 min. Ninhydrin values according to Moore and Stein[8] were determined on 0·5 ml. aliquots from each sample. The distribution curve is shown in Fig. 2. The large peak in the middle corresponds to lysine-vasopressin.

This is part of a programme on the development of zone electrophoresis methods at this Institute. It has been financially supported by the Swedish Natural Science Research Council, the Rockefeller Foundation, the Wallenberg Foundation and the U.S. Department of Army, through its European Office, under contract number *DA*–91–508–*EUC*–287.

Neutron Production and Temperature in ZETA

It is assumed that thermalization and high temperature have been achieved in ZETA[1], although theoretical considerations demand a much longer period than that available for the process to take place[2]. This discrepancy between apparently observed and the theoretically expected thermalization time may be due to unknown processes occurring which speed up the process of thermalization[2]. This explanation, however, does not seem to be valid. Moreover, it is possible to explain most of the observed facts, if one assumes a 'betatron type' of acceleration of deutrons in ZETA, for the following reasons:

(*a*) Theoretical and experimental work[3–5] have shown that under suitable conditions 'run-away electrons' are produced in gas discharges; that is, under certain conditions the cross-section for electron – ion collision is small. This implies that under these conditions the ions can move freely through the electrons with mean free paths much larger than those computed from considerations of plasma density.

(*b*) Using the method of estimating critical velocity for 'run-away electrons'[5] and the equations of Spitzer[6], the critical energy required for ions to be continuously accelerated against ion–ion collision losses is $W = 3\cdot2 \times 10^{-14}\, n/V$ electron volts, where n is the number of ions per cm.³ and V is the electric field in volts per cm. In ZETA, with $n = 6 \times 10^{13}$ and initial value of $V = 2$ volts per cm., $W = 1$ eV. Thus, even at room temperature there is an appreciable number of ions (about 10^{8}) out of a total of about 10^{19} ions in ZETA, which could be accelerated. The number of neutrons produced per pulse is also of a similar order; but this may be just a coincidence. The initial adiabatic compression could contribute still further to this number of eligible ions.

Once the ions are in a condition suitable for acceleration, an average field of 1 V./cm. could accelerate the ions to 60 keV. in 0·5 m.sec. or to 240 keV. in 1 m.sec. The azimuthal magnetic field due to 2×10^{5} amp. is sufficient to confine ions of even higher energy; but ions of very high energy may not be produced because of the chance of ion loss by ending in nuclear reactions with the large number of relatively stationary ions.

If this mode of ion acceleration is accepted, it is easy to resolve the difficulties in explaining most of the facts observed with ZETA.

(1) Some of the deutrons undergo 'betatron type' of acceleration and gain enough energy in the observed time of about 0·5–1 m.sec. and produce neutrons by colliding with the large number of relatively slow-moving ions, as explained above. The difficulty about thermalization time[3] automatically vanishes.

(2) The anisotropy of neutron energy observed by means of photographic emulsion technique cannot be explained by any process of thermalization; but it is a necessary corollary of this method of acceleration of ions. (This experiment was mentioned during a lecture at the Tata Institute on May 19, 1958, by Dr. T. E. Allibone, to whom this possibility of acceleration of ions in ZETA was briefly mentioned.)

(3) The oxygen and nitrogen atoms in the discharge could gain random energy perpendicular to the discharge axis due to scattering by accelerated deutrons, and this could explain the observed Doppler broadening of their spectral lines when observed perpendicular to the discharge axis. If these ions also acquire a large drift velocity due to the collision of deuterons and the electric field, observation of the spectrum in a direction tangential to the discharge should reveal a Doppler shift as well.

(4) The observed decrease in neutron production with any increase of initial gas pressure could be due to the increase in the critical energy, which will reduce the number of ions eligible for acceleration.

In the light of this explanation, ZETA is a zero energy toroidal accelerator somewhat similar to that proposed by Budker[7]. The ions move in a direction opposite to that of the electrons and behave like a one-dimensional gas which is not in thermodynamic equilibrium and hence not obeying Maxwell's distribution law. Temperature assignment to such a gas has only dubious value. Nevertheless, this does not preclude the possibility of a fusion reactor of the type of ZETA, even though it may never be a truly thermonuclear reactor.

I am grateful to my colleagues, Mr. S. S. Bhave, Dr. A. S. Divatia, Mr. M. K. Mehta and Dr. A. P. Thatte, for stimulating discussions.

Ductility of Chromium deposited from Molten Chloride Baths

Some time ago[1], we reported that chromium was deposited from certain molten chloride baths as hexagonal crystals which are transformed on cooling to the cubic form, as shown by X-ray examination.

In our further study of ductility in these crystals, we have found that while a low oxygen-level (less than 0·02 per cent) is necessary for ductility, the position of the oxygen in the lattice is also important. This position is, we believe, reflected in electrode potential. With a given oxygen content ductility is always associated with lower electrode potential against pure chromium. The hexagonal crystals show a break in the electrode potential temperature curve when measured against ordinary chromium. This is shown in Fig. 1. Ductility is thought to be determined by the mechanism of transformation from the hexagonal to the cubic form, and particularly by the distribution of impurities in the new lattice.

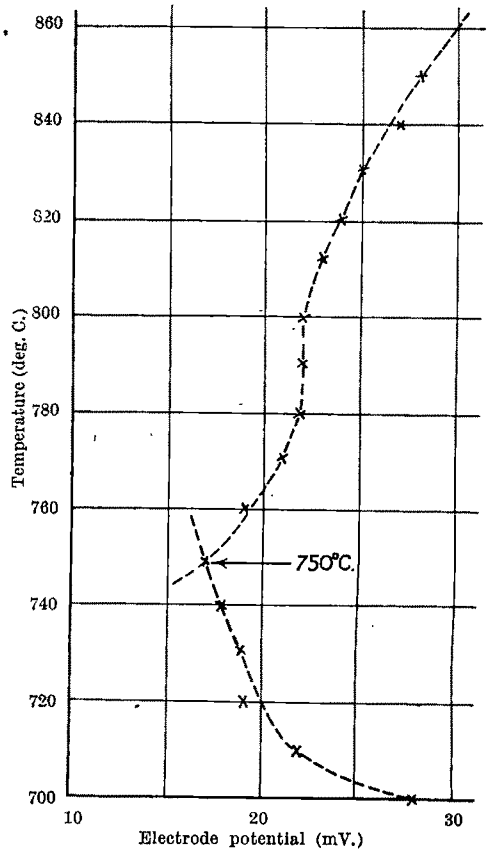

Fig. 1. Cooling curve of our chromium against commercial chromium

If crystal growth takes place along an uninterrupted screw axis, then the chromium is ductile by deformation along these axes. The photomicrograph (Fig. 2) is of a platelet of chromium from fused salt electrolysis bent 135° and cut and polished on the plane of the original platelet. The etch is electrolytic.

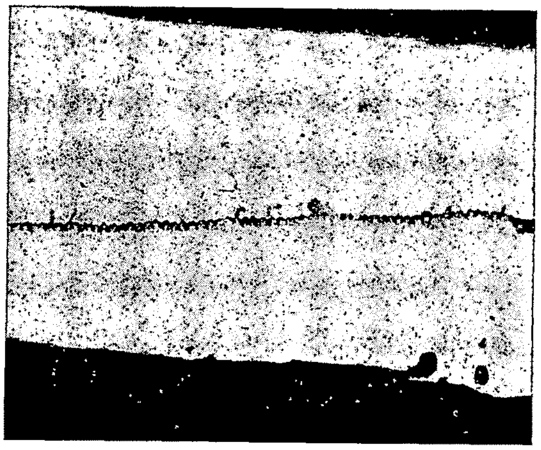

Fig. 2. Platelet of chromium, bent 135° and cut and polished on the plane of the original platelet. (× 75)

Many such screw 'deformations' occur in bending chromium platelets of this kind.

A Highly Sensitive Chemical Dosimeter for Ionizing Radiation

An aqueous dosimeter capable of measuring radiation doses of less than 100 rads would be an extremely useful tool in the field of radiobiology. Although doses of a few rads can be accurately measured using the resorcinol-stabilized tetrachlorethylene-dye systems[1], such systems where the radiation-induced reaction proceeds by a chain mechanism exhibit certain undesirable characteristics. An alternative to the radiation-induced chain reaction involves the measurement of extremely small amounts of an irradiation product by means of a sensitive analytical technique. Some idea of the extreme sensitivity required is obtained from the fact that a dose of 100 rads will produce approximately 10^{-7} moles of product per litre of solution, assuming a reasonable production-rate of unity for $G_{\text{prod.}}$ (that is to say, 1 molecule of product formed per 100 eV. absorbed). An analytical method capable of accurate measurement at such high dilution is spectrophotofluorometry. The production of salicylic acid (which fluoresces in aqueous solution) in irradiated aqueous solutions of benzoic acid seemed to merit investigation, especially because this reaction had been proposed[2] as suitable for chemical dosimetry.

During irradiation a mixture of the three isomeric hydroxybenzoic acids is produced in the ratio of 5 : 2 : 10 for the *o* : *m* : *p* isomers respectively[3]. However, at 400 mμ (exciting wave-length 290 mμ) the fluorescent intensity of the *m* and *p* isomers is small compared with that of salicylic acid and can be neglected. Diphenyl has also been identified as a radiation product, but it does not fluoresce at 400 mμ if excited at 290 mμ. The fluorescent intensity of salicylic acid solutions is a linear function of concentration in the range 10^{-7}–10^{-8} *M*, and is independent of acidity from *p*H 5–11. Since the reproducibility of the measurements was only about ± 10 per cent, presumably because of the fluctuations in the intensity of the light source of the Aminco–Bowman spectrophotofluorometer, each experimental run was calibrated separately in the following manner. The fluorescent intensities of two standard salicylic acid solutions were measured immediately before and immediately after measurements were carried out on a series of irradiated solutions, and the salicylic acid concentrations in the latter solutions were computed using the average value of the 'fluorescence coefficient':

$$\text{Fluorescent coefficient} = \frac{\text{fluorescent intensity of standard}}{[\text{salicylic acid}]}$$

All dose-rates were determined using the ferrous sulphate $-0{\cdot}8\,N$ sulphuric acid dosimeter[4]. Corrections for the decreased energy absorption in water were made as described previously[5].

From Fig. 1 it is seen that the concentration of salicylic acid in irradiated $10^{-4}\,M$ calcium benzoate solutions (*p*H 5) increases in a linear fashion with dose of X- and γ-radiation over the range 0–100 rads, and is independent of dose-rate over the range 4–50 rads/min. For a given dose the fluorescent intensity is almost identical for cobalt-60 and cæsium-137 γ-rays. The rates of salicylic acid production expressed as $G_{\text{Sal.}}$ were computed to be:

Incident radiation	Co^{60} γ-rays	Cs^{137} γ-rays	300-kV. peak X-rays	100-kV. peak X-rays
Effective energy (MeV.)	1·25	0·66	0·16	0·05
$G_{\text{Sal.}}$	0·63 (15·5)	0·63 (15·5)	0·63 (15·5)	0·52 (13·8±0·5)

The values in parentheses refer to the values of the oxidation yield of the ferrous sulphate dosimeter used in the computation of $G_{\text{Sal.}}$

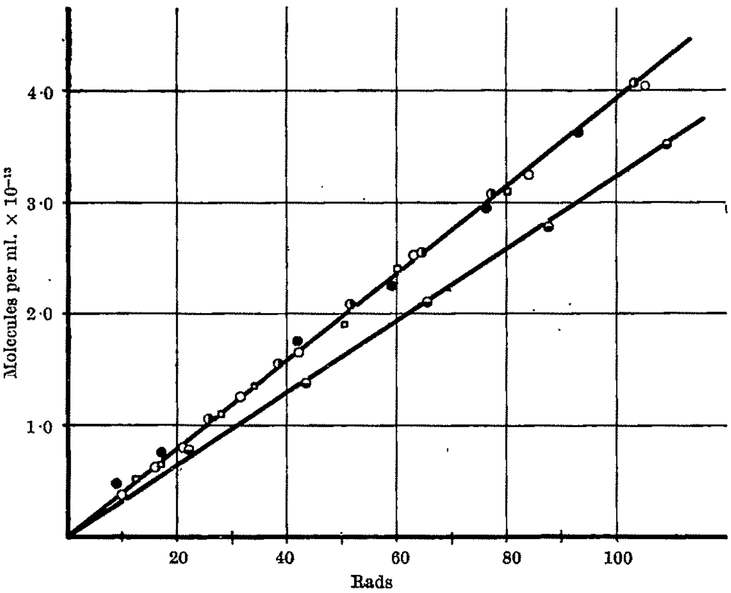

Fig. 1. ⊖, 100-kV. peak X-rays (20 rads/min.); □, 300-kV. peak X-rays (17 rads/min.); ●, 600-keV. cæsium-137 γ-rays (4 rads/min.); ○, 1·25-MeV. cobalt-60 γ-rays (20 rads/min.); ◑, 1·25-MeV. cobalt-60 γ-rays (50 rads/min.)

It is interesting to note that the $G_{\text{Sal.}}$ values are in reasonable agreement with the value of 0·73 deducible from the results of Weiss and co-workers[3] on the irradiation of $1{\cdot}6 \times 10^{-2}\,M$ solutions of benzoic acid at *p*H 5 with 200-kV. peak X-rays.

These preliminary experiments indicate that doses of electromagnetic radiation in the range 5–100 rads may be accurately measured (about ± 5 per cent) from the fluorescence induced in calcium benzoate solutions. It is hoped to extend these experiments to the measurement of doses below 5 rads.

FORTHCOMING EVENTS

Monday, September 15

Institute of Metal Finishing (at Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Prof. Ernst Raub (W. Germany): "Recent Research on Macro- and Micro-Throwing Power".

Wednesday, September 17

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Dr. T. Salomon (Institut Français du Pétrole): "Harmful Effects of Electrostatic Charges on Machinery and Lubricating Oils".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Research Associate in Upper Atmospheric Physics, for duties including experimental and observational research on the airglow and auroræ—Prof. D. R. Bates, F.R.S., Department of Applied Mathematics, The Queen's University, Belfast (September 20).

Lecturer or Assistant Lecturer (with interests in palæontology, stratigraphy or sedimentology) in Geology at St. Salvator's College—The Joint Clerk to the University Court, College Gate, St. Andrews (September 22).

Senior Scientific Officer (with a first- or second-class honours degree, preferably in biochemistry, and at least three years' post-graduate experience, or equivalent qualifications) at the Royal Air Force Institute of Pathology and Tropical Medicine, Halton, for work on clinical biochemical research, development and application of medical biochemical techniques related to aviation pathology and routine chemical use, and to give some assistance in teaching—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.594/8A (September 29).

Director (with good academic qualifications and of proven scientific leadership and administrative ability) of the Cawthron Institute, to develop researches primarily into plant nutrition problems of horticulture and agriculture—The Managing Secretary, Cawthron Institute Trust Board, Box 29, Nelson, New Zealand, or the New Zealand High Commissioner, 415 Strand, London, W.C.2 (September 30).

Lecturer (with an honours degree and professional experience, preferably with special interest in concrete and reinforced concrete) in Civil Engineering—The Registrar, King's College, Strand, London, W.C.2 (September 30).

Lecturer or Assistant Lecturer in Economics—The Registrar, University College of North Staffordshire, Keele, Staffs (September 30).

Lecturer in Inorganic Chemistry at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

Senior Lecturer or Lecturer in Mathematics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (September 30).

Senior Lecturer or Lecturer in Geology at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 4).

Chair of Soil Science in the Institute of Agriculture, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 8).

Lecturer in Agricultural Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 10).

Junior Lecturer in Botany—The Registrar, Trinity College, Dublin (October 11).

Professor of Mathematics at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 13).

Lecturer or Assistant Lecturer (able to teach in comparative physiology) in Zoology at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

Senior Lecturer/Lecturer in Geography at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 14).

Senior Lecturer in Anatomy (Gross Anatomy) at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (November 30).

Assistant Conservator of Forests (with a university degree in forestry, and preferably experience or training in surveying) in Nyasaland—The Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD.61/4/01.

Assistant Lecturer in Mathematics—The Secretary, Royal College of Science and Technology, Glasgow.

Chair of Metallurgy—The Secretary, Royal College of Science and Technology, Glasgow.

Chemist, Scientific Officer grade (graduate with a good first- or second-class honours degree, preferably with a knowledge of high vacuum techniques), to undertake research with radioactive gases involving the separation of mixtures and thermal diffusion of gaseous isotopes—The Group Recruitment Officer, United Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Didcot, Berks, quoting 1195/34.

Entomologist (with a good honours degree in natural science and some research experience in entomology) with the Department of Agriculture, Trinidad, to carry out research on biology and control of insect pests of coconuts and to co-operate in assessing their importance as vectors of red ring disease—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/38/01.

Lecturer (with a good honours degree in chemistry, or F.R.I.C., preferably with the desire and ability to undertake research) in Inorganic Chemistry, at Coventry Technical College, to teach subject to Grad.R.I.C. standard—The Director of Education, Council Offices, Coventry.

Zoologist (with a good honours degree and an interest in parasitology, preferably with a knowledge of chemistry) in the Helminthology Department—The Head, The Wellcome Laboratories of Tropical Medicine, 183–193 Euston Road, London, N.W.1.

ION EXCHANGE RESINS FOR CHROMATOGRAPHY

A complete range of "Zeo-Karb 225" and "De-Acidite FF" ion exchange resins for chromatographic separations and other analytical purposes is now being produced by The Permutit Company Ltd. A new production unit has been established especially for this purpose. Details of the resins are shown in the table on the right.

The crosslinking of "Zeo-Karb 225" cation exchange resins is given in terms of nominal weight percentage of divinylbenzene in the hydrocarbon polymer. The corresponding weight swelling or water regain is also given.

Only the weight swelling, or water regain is specified for the "De-Acidite FF" because extra crosslinks, in addition to those originally placed in the hydrocarbon structure, are introduced during manufacture. It is thus not possible to produce "De-Acidite FF" in as wide a range as "Zeo-Karb 225" because materials with very high water regain are difficult to manufacture reproducibly.

"ZEO-KARB 225"

THE GRIFFIN THERMOSTATIC OVEN

FOR ALL-ROUND THERMAL EFFICIENCY

The Griffin Thermostatic Oven has been designed for use in Chemical, Metallurgical, Bacteriological and Pathological laboratories. It is ideal for all drying and sterilizing work.

Easy to clean and resistant to staining, the exterior has a durable cream finish, the interior being aluminium. The door and casing are heavily lagged and a combined thermometer support and rotatable ventilator is fitted in the roof.

Simple to operate, the base controls comprise an on/off switch, pilot lamp and sensitive slow-motion thermostat. A temperature gradient of ±1° C., over the range from about 5° C. above ambient to 300° C., is constantly maintained. No measurable temperature variations at any one point can be detected.

Low power consumption is achieved by the most careful design and disposition of the heating elements. The chamber space is 26 cm. by 36 cm. diameter... ... ... £62 0 0

LECTURES AND COURSES

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF PHYSICS

Session 1958-59: Postgraduate Evening Courses are resumed on September 22, 1958. Subjects available: Acoustics and Vibration Physics; Nuclear Physics; Optics; Physical Electronics; Quantum Mechanics; Semi-conductors: Electromagnetism. Ancillary courses include Electronic Circuits. Enrolment: Tuesday, September 16, and Wednesday, September 17, 6 to 8 p.m.

Further details and application forms from the Secretary, Physics Department, Chelsea College of Science and Technology, Manresa Road, S.W.3.

SCHOOL OF ORIENTAL AND AFRICAN STUDIES

UNIVERSITY OF LONDON, W.C.1

MODERN ARABIC

An Intensive Introductory Course will be held from October 1 to December 10, 1958. Instruction will be given in basic grammar, translation, Press and Radio Arabic, the grammar of Colloquial Arabic, and general Middle Eastern topics. Fee: £40 10s. per head.

Inquiries to the Organizer of Special Courses.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMISTRY

ANALYTICAL METHODS

A series of postgraduate lectures on more recent analytical techniques will be held during the Autumn Term on Tuesdays at 7 p.m., commencing on October 7, 1958. The topics will include spectroscopic methods, solvent extraction, square wave polarography, radio-activation, isotopic dilution, inorganic paper chromatography, silicate analysis, nuclear magnetic resonance and organic sub-micro analysis.

A leaflet giving full details, and an application form, may be obtained from the Head of the Chemistry Department, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

OFFICIAL APPOINTMENTS

DIRECTOR

CAWTHRON INSTITUTE, NELSON, N.Z.

Applications for the above position are invited from those who are academically well qualified, of proven scientific leadership and administrative ability, to develop researches primarily into plant nutrition problems of horticulture and agriculture. Salary scale £2,000 to £2,250.

Details are obtainable from the Managing Secretary, Cawthron Institute Trust Board, Box 29, Nelson, N.Z., or the N.Z. High Commissioner, 415 Strand, London, with either of whom applications close on September 30, 1958.

SENIOR SCIENTIFIC AND SCIENTIFIC Officers, required at Government Communications Headquarters, Cheltenham, for telecommunications and electronic research in following fields: V.H.F. receiver design and microwave techniques; propagation trials; applications of semi-conducting devices; high speed electronic switching; data storage and handling: computer programming, and operational research. Candidates must normally be natural born British subjects of natural born British parents. First- or second-class honours degree in physics, mathematics or engineering or equivalent, at least three years' postgraduate experience for Senior Scientific Officer. Salaries for men (provincial rates) Senior Scientific Officer, £1,130 to £1,330; Scientific Officer, £595 to £1,050 (according to age and qualifications). Appointments unestablished but opportunities to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A147/8A.

CHEMIST REQUIRED BY NATIONAL Coal Board's Mining Research Establishment, Worton Hall, Isleworth, Middlesex, to assist in investigations into problems associated with the corrosion and deterioration of steel and other materials in coal mining conditions, and their protection by metallic or organic coatings. Applicants should have a good honours degree in chemistry. Appointment (superannuable) within inclusive scales £690 to £1,202 male, £674 to £1,147 female, depending on qualifications and experience. Five-day week; generous sick leave and holidays; staff canteen.—Write to Personnel Officer (X.1191/2) at above address, for application form which should be completed and returned by September 25, 1958.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF LAND RESEARCH AND REGIONAL SURVEY

APPOINTMENT OF ECOLOGIST

Applications are invited for appointment to a position of Ecologist with the Division of Land Research and Regional Survey. The appointee will be a member of the Division's scientific unit which, for the past twelve years, has been conducting potentiality surveys mainly in undeveloped regions. Studies in the geology, geomorphology, pedology, botany and climatology of the regions are co-ordinated, and the officer will be expected to contribute to composite reports and to publish individual specialist papers. The appointee will make field studies with the unit for three to four months most years and the rest of the year at headquarters in Canberra, A.C.T., for compilation of maps, reports and papers dealing with the field surveys and subjects arising from them. The work will involve extensive use of aerial photographs, and their interpretation, and travel to many parts of Australia. Applicants should have a university honours degree in science, or agricultural science with botany, as a major subject, and research and field experience in plant ecology. Training in allied subjects such as soil science is desirable. The appointee will be classified as Research Officer, £A.1,326 to £A.1,951 per annum, or Senior Research Officer, £A.2,061 to £A.2,336 per annum, and commencing salary will be determined according to qualifications and experience. The appointment will be conditional upon a satisfactory medical examination and appointment carries with it Commonwealth Superannuation Fund or Commonwealth Provident Account privileges. Fares to Australia, including those of wife and dependent family, will be provided by the Organization. Details may be discussed with the undersigned.

Applications, quoting Appointment No. 570/64, and stating full name, place, date and year of birth, nationality, marital state, present employment, details of qualifications and experience, and of war service, if any, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach the undersigned from whom further particulars may be obtained by October 11, 1958.

E. J. DRAKE,
Chief Scientific Liaison Officer.
Australian Scientific Liaison Office,
Africa House, Kingsway, London, W.C.2.

HAMPSHIRE EDUCATION COMMITTEE

FARNBOROUGH TECHNICAL COLLEGE

Principal: Mr. R. D. Peggs, O.B.E., M.A., M.I.Mech.E., F.R.Ae.S.

Applications are invited for the following posts:

(1) Assistant Lecturer (Grade B) in Electrical Engineering to assist in courses for O.N.C. and H.N.C. in Electrical Engineering. Industrial experience preferable.

(2) Assistant Lecturer (Grade B) in Applied Physics for O.N.C. course developing to H.N.C. level in Session 1959/60. Industrial experience preferable.

The salary for the posts will be in accordance with the Burnham Scale—Grade B (men) £650 by £25 to £1,025 with the usual allowances for training, qualifications and industrial experience, e.g., £125 for a good honours degree.

Further particulars and application forms may be obtained from the Principal, Farnborough Technical College, Boundary Road, Farnborough, Hants, to whom they should be returned as soon as possible.

R. M. Marsh, County Education Officer, The Castle, Winchester.

UNIVERSITY OF MALAYA

SINGAPORE

Applications are invited for (A) Lectureship or (B) Assistant Lectureship in Biochemistry. Salary scales: For medically qualified candidates (A) £1,295 by £49 to £1,442/£1,540 by £56 to £1,988 per annum. (B) £1,148 by £49 to £1,246 per annum. For non-medically qualified candidates (A) £1,148 by £49 to £1,442/£1,540 by £56 to £1,820 annum. (B) £1,001 by £49 to £1,099 per annum. Entry point determined by qualifications and experience. Allowances: expatriation in range £280 to £308 per annum, cost of living in range £210 to £560 per annum. Passages for appointee, wife and children under 12 years. Part-furnished quarters at reasonable rent. Provident Fund Scheme.

Detailed applications (six copies), naming three referees by October 31, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

METALLURGICAL RESEARCH

THE UNITED KINGDOM ATOMIC ENERGY AUTHORITY

(Industrial Group)

requires

SCIENTISTS

in its

RESEARCH & DEVELOPMENT LABORATORIES

(a) AT CULCHETH, WARRINGTON, LANCASHIRE

to join a team which advises on the choice of materials and the specification and approval of methods of construction of pressure vessels and ancillary equipment for use in nuclear reactors. Collaboration with Electricity and Inspection Authorities will be involved. (Ref. 2565).

A first- or second-class honours degree, or equivalent, together with extensive experience supported by adequate laboratory investigation, are essential.

Salary between

£1,460 to £2,080,

according to qualifications and experience.

Supporting staff are also required to assist in this work. (Ref. 2577). A higher school certificate, or equivalent, with mathematics or a science subject as principal subject, is essential, and higher qualifications would be an advantage. Good relevant experience is also required.

Salary between

£1,360 to £1,630,

according to qualifications and experience.

(b) ALSO AT CULCHETH

to devise and control experimental programmes on all aspects of steels for reactor pressure circuits. Interpretation of results on currently used steels and the development of improved steels and welding processes in conjunction with industry will form an important part of the work. (Ref. 2566).

A first- or second-class honours degree, or equivalent, together with considerable appropriate experience, is essential.

Salary between

£1,460 to £2,080,

according to qualifications and experience.

(c) AT SALWICK, PRESTON, LANCASHIRE

to be responsible for development work on the powder metallurgy of refractory metals and allied processes. (Ref. 2567).

An honours degree, or equivalent, in metallurgy, together with experience in powder metallurgical processes, is essential. A knowledge of the techniques and hazards associated with the handling of radioactive metals is desirable.

Salary for this post will be between

£1,300 to £1,740,

according to qualifications and experience.

Contributory Pension Scheme.

Housing or assistance towards legal expenses on house purchase may be available.

Send postcard for application form, quoting appropriate reference, to Recruitment Officer, U.K.A.E.A., I.G.H.Q., Risley, Warrington, Lancashire.

Closing Date: September 29, 1958.

THE ROYAL COLLEGE OF SCIENCE AND TECHNOLOGY,

GLASGOW

(Affiliated to the University of Glasgow)

CHAIR OF METALLURGY

The Governors of the Royal College of Scienc and Technology invite applications for the Chai of Metallurgy, which will become vacant on Apri 1, 1959, on the retirement of the present holde Professor R. Hay. The salary is on a scale £2,40 by £100 to £2,700. Forms of application and particulars of the appointment may be obtained fron the Secretary.

"BELLING-LEE"

MINIATURE

Unitors

WITH 8 or 12 CONTACTS

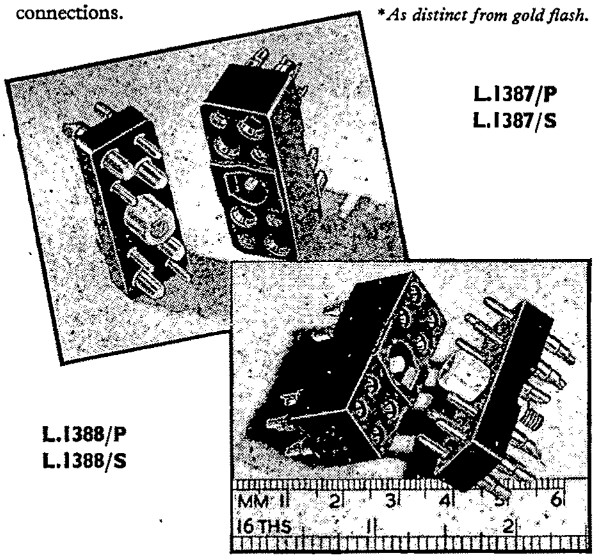
For the inter-connection of units in one assembly where space and weight considerations prevent the use of standard Unitors, we have designed and developed this new range of Miniature Unitors in the "Domino" series.

Moisture-and tracking-resistant nylon-filled phenolic material is used for body mouldings. Pins are of gold-plated* or silver-plated brass. Sockets of high grade beryllium copper, slotted to ensure good contact with pin.

Each assembly has a shaped centre pin which polarizes the plug on engagement, and the back of this pin carries an 8BA stud for mounting the Unitor on chassis or panel.

Various pin combinations and arrangements are possible within the same chassis cut-out, to give a highly flexible method of obtaining an individual connection for each group of inter-connections.

**As distinct from gold flash.*



L.1387/P.	PLUG, with four small and four large pins
L.1387/S.	SOCKET FOR L.1387/P.
L.1388/P.	PLUG, 8-pole (8 small pins)
L.1388/S.	SOCKET FOR L.1388/P.
L.1389/P.	PLUG, 12-pole (12 small pins)
L.1389/S.	SOCKET FOR L.1389/P.

These miniature Unitors and other new developments are fully described in the Supplement (No. P490/H) to our General Catalogue: copies are available on request.

POLICY, PURPOSE AND PARTNERSHIP IN EDUCATION

SIR WILLIS JACKSON'S presidential address to Section L (Education) of the British Association on the partnership between industry and education laid emphasis on the conception of partnership in the sense that industry and education should each interest itself in the work of the other and, where appropriate, contribute to the work of the other, as well as fulfil the responsibilities which directly accrued to it within its own domain. Industry's responsibility was analysed in some detail from both points of view; but, while Sir Willis did not discuss to any extent the specific parts to be played by the schools, the technical colleges and the universities, for example, his address had a much wider interest and directed attention to aspects of technical and technological education which, as some other addresses at the British Association meeting have indicated, are recognized as of increasing importance. Like so many others, he insisted that the supply of well-qualified and well-trained teachers is the most crucial aspect of all our educational plans; but the partnership he advocates is put in its proper perspective, so that the responsibilities of the government and of the community itself can no less clearly be seen.

Sir Willis considers that industry has already gone some way towards convincing the schools that industry can offer those with a sense of vocation as satisfying a career as the 'learned' professions, which have traditionally attracted a dominant proportion of the ablest young people of Britain. This means, he believes, that industry is coming to be seen not merely in terms of machines and scientific and technical processes, but also in terms of men of character and stature, and of the opportunities it provides both for the exercise of scientific and technical skill and for co-operation in service and human relations. None the less, he points out that the importance of the supporting contribution has been insufficiently recognized, and that we have given too little attention to the educational needs of the much larger body of technicians and craftsmen. Here, too, technical change is not simply altering the balance of the labour force and increasing the numerical importance of the scientific, technological and technical staff, of the skilled men engaged on service and maintenance, relative to direct labour. It demands also increasing versatility, adaptability and capacity for understanding changing situations and points of view.

To reach the consequent higher level of scientific knowledge and attainment in an increasing proportion of industrial personnel and extended and broader education for all, industry, Sir Willis suggested, carries a considerable responsibility, and he refers with appreciation to the value of the work of the Industrial Fund for the Advancement of Scientific Education in Schools. Nor is this the only point at which his address reinforces Prof. F. A. Vick's argument about the contribution of the university to education in a technological age. He commented, for example, on the desirability, in day-time release from employment, for some time in attendance at technical colleges to be available for participation in corporate life within the college and for the continuance of general education. Reinforcing the recommendation of the Committee on the Supply and Training of Teachers for Technical Colleges over which he presided, he urged the need for more industrial concerns to take active steps to promote close contact with full-time members of the college staffs and to increase the absolute contribution made by part-time teachers; in this connexion he touches on the importance of status and of associating some such teachers both with advanced teaching and with the formulation of academic policy.

Here, as when he referred to the importance of bringing representatives of the highest ranks of industry into closer association with the governing bodies and advising committees of the technical colleges, Sir Willis indicated ways in which we can more effectively deploy the full strength of our existing teaching strength, rather than increase its numerical strength. It could well be said that concern with obtaining the fullest value both from the present educational effort and the existing scientific and technical manpower in Britain was one of the keynotes of this address. That, for example, is the implication of Sir Willis's reference to the importance of supporting technicians and craftsmen and no less of his suggestion that sixth-form grammar school boys should not be encouraged to remain at school to the age of eighteen with engineering as their objective, if they have shown little aptitude for the traditional subjects of grammar school curricula. Unless boys are capable of undertaking advanced work in physics and mathematics with fair promise of success at Advanced Level of the General Certificate of Education, Sir Willis believes it to be far preferable for them to enter industry at an earlier age and pursue their studies within the technical colleges.

This engineer's conception of fitness for the purpose, of choosing the tool for the job which pervades the whole address, is one that is all-important if the nation is to obtain full value from its present educational effort—already some £740 million a year and, according to Sir Alexander Fleck, needing to be increased to some £1,200 million—and it supplies the decisive reason for attention to the apprenticeship system, the discussion of which occupied a large part of Sir Willis's address.

It is here that he regards the responsibility of industry as most direct, and he was highly critical of the failure of the Carr Committee to go further than to recommend a purely advisory national apprenticeship council, the function of which would be to keep representative organizations of employers and workers informed of progress and to collect and disseminate information about those aspects of training common to more than one industry. Something much more fundamental is urgently required, including considerable changes of attitude among both employers and trade unions, an extensive building programme and solution of a difficult staffing problem. The position is one that cannot be left to drift for, as once again we are reminded, the changing educational pattern means that from now on an increasing proportion of the boys of high natural ability who, in spite of deficiencies in their early training, have provided excellent craftsmen in the past, will remain at school beyond the age at which at present industry recruits its craft apprentices. A lowering in the quality of the entrants to craft apprenticeship is thus to be expected at a time when the raising, not lowering, of the standard of craft skill is imperative.

In this situation the deference of the Carr Committee to traditional practices and embedded prejudices on both sides could be disastrous, and such deference is the more disturbing in that Lady Gertrude Williams has already analysed the situation searchingly and constructively in her book "Recruitment to Skilled Trades". Sir Willis indicated the range of questions which her analysis has raised, but he declined to discuss them because he believes that individual opinion is unlikely to make any impact in the continued absence of a national body with executive powers and the financial means for exercising those powers effectively. Moreover, he pointed out that, so far back as 1944, the report of a conference of representatives of the Manchester and District Committees of the Engineering and Allied Employers National Federation, the Amalgamated Engineering Union, the major engineering institutions and the Regional Advisory Council for Technical and Other Forms of Further Education had recommended the establishment of a national engineering apprentice council as a central directing body, and of associated regional councils with defined responsibilities in their respective areas. These responsibilities for the organization and administration of training schemes included estimating the future needs of industry in the area and adjusting the intake of apprentices to training schemes accordingly; advising on the establishment, equipment, staffing and maintenance of apprentice training centres to meet the regional needs; co-operation with employers in placing apprentices on completing their courses; approval of facilities for further training; interest in the development of non-vocational interests; and the issue of certificates of competency on completion of apprenticeship. The report recognized the need for a detailed investigation as a basis for any such scheme, but equally the urgent need to face and solve the difficulties involved in implanting such proposals. It was confident then that it was within the power of Great Britain to ensure that its system of technical education, both in its teaching staff and in its buildings, was made adequate to the demands of the next decade.

A decade has been lost, but we need not be more pessimistic than in 1944 as to our ability to develop the necessary facilities if we are willing to apply the financial and other resources required, and resolute to deal firmly with whatever prejudices or obsolete practices obstruct such development. It means that the conditions laid down by Sir Willis Jackson must be faced frankly and resolutely handled as impartial inquiry and constructive thought may indicate. What duration of training, suitably organized and conducted, is really necessary for the different crafts, as against the universal five-year period from sixteen to twenty-one years of age for all crafts? Should the age of entry to craft apprenticeship be raised to permit the entry of boys who have pursued general education at school beyond the age of sixteen? Should early stages of training be carried out in training centres on a full-time basis where continued general education could also be provided, and if so whether such centres could be organized co-operatively by groups of firms on an adequate, nation-wide basis, or whether they must be provided by the local authorities? How to assess the numbers of recruits for the various crafts, and how to test competence—these are all questions demanding searching and impartial inquiry in the light of present conditions and trends, and resolute urgent action on the basis of such inquiry.

Finally, there is the question of finance. Whether a national fund should be provided jointly by the State, the local education authorities, employers and trades unions—and on what basis—demands inquiry, as does the question of how individual firms should be assisted to bear the cost of running their own training schemes. It can at least be predicted with confidence that whatever the basis to which such inquiry may point, it will offer a contribution to the economics of education out of all proportion to the direct expenditure involved. Running through the papers on varied aspects of education contributed to the Glasgow meeting of the British Association has been a note of concern that in the growing scale of expenditure on education, increasing care should be taken to see that the nation receives full value for that expenditure. Attention to this question of the training of technicians and apprentices will involve some further direct expenditure; but that expenditure is likely to be offset many times over by the elimination of the waste involved in the persistence of the present obsolete practices, quite apart from the direct gain in the more efficient and effective use of the more highly trained scientist and technologist whose work it is a primary function of the technicians and craftsmen to support and extend.

CHEMICALS AND CANCER

Mitotic Poisons and the Cancer Problem

By Dr. John J. Biesele. Pp. viii+214. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1958.) 37*s.* 6*d.*

A FEW years ago, the editors of "Tabulæ Biologicæ" asked cytologists and geneticists in various countries to provide material for quantitative tables on the effects of mitotic poisons and chemical mutagens. Several, possibly all, of those approached were of the opinion that the time for such a tabulation had not yet come in spite—or rather because—of a tremendous and bewildering wealth of data. While tabulation at this stage may do more harm than good by its false suggestion of orderliness and congruence in a field of much conflicting evidence, an impartial review was needed to summarize the present position and point out the most useful and promising lines for future experimentation.

Everyone interested in the subject of mitotic poisons—and this includes plant breeders and oncologists as well as cytologists, geneticists and biochemists—must be grateful to Dr. Biesele for having undertaken this task. The great number of literature references—nearly a thousand, including many German ones—shows what a tremendous mass of material has been compressed into less than 200 pages. It was not to be expected that this degree of condensation would result in an easily readable book, but there is no lack of clarity and precision. If, in spite of this, the facts are often confusing, this is not Dr. Biesele's fault. One only needs to look at the evidence for and against inhibition of deoxyribonucleic acid synthesis as the primary effect of alkylating agents, or at the description of the highly complex and variable interactions between purines to realize how far we are still removed from insight into the ways in which mitotic poisons act. It is natural that every group of investigators favours interpretations which agree with their own particular results, and thus conflicting theories have been built on conflicting facts. Dr. Biesele impartially reports both facts and theories and never falls into the error of facile over-simplification. A more personal point of view would almost certainly have made the book more readable, but it would probably have destroyed its prime value as an objective summary and source of references.

The only type of evidence which is almost wholly neglected is the purely genetical one. Like most cytologists, Dr. Biesele does not seem to recognize the fact that a genetically established chromosomal change is just as real as one seen under the microscope, probably more so. This bias has resulted in a somewhat incomplete report on the chromosomal effects of alkylating agents, and in the complete omission of formaldehyde as a substance which in *Drosophila* produces all known types of chromosome rearrangement. Incidentally, drosophilists would not agree that a chemical (3,6-disodium endohydrophthalate) which produced scarcely 1 per cent sex-linked lethals in *Drosophila* is "strongly mutagenic".

The data are grouped according to various types of mitotic effect: poisoning at prophase and interphase; poisoning of the chromosomes; poisoning at metaphase and later stages. Since these effects may overlap and many substances act in more than one way, a chemical classification might have been preferable; a good subject index, however, makes it easy to follow any particular substance or group of substances through the whole mitotic cycle. As indicated in the title, the importance of mitotic poisons in cancer therapy is stressed throughout the book. Dr. Biesele's own research on substances which act preferentially on tumour cells is here of special interest. The highly important role of mitotic poisons in cancer therapy, coupled with the fact that so far no really curative chemicals have been detected, adds great practical significance to this review.

C. Auerbach

NAPHTHALENE

The Chemistry and Technology of Naphthalene Compounds

By Norman Donaldson. Pp. xv+512. (London Edward Arnold (Publishers), Ltd., 1958.) 90*s.* net

THIS book is concerned with the preparation and manufacture of naphthalene derivatives, especially those, of course, involved in the manufacture of dyestuffs. Its most important feature can be illustrated by reference to the aminonaphtholdisulphonic acids: each of the thirty-six known isomers is listed together with at least an indication of its preparation, while the properties and manufacture of the more important, for example H-acid, are described in detail. The available information (industry broods over the more intimate) concerning such compounds seems to be assembled in this book, which, therefore, is valuable for reference purposes. Included also is discussion of the distribution of electrons in naphthalene and the mechanism of sulphonation, nitration, diazotization, diazo-coupling, the Bucherer reaction and other substitution processes. Unfortunately, these topics seem to place the author on unfamiliar ground, for there are comments of the type "However, negative substitution of amines also reduces their basicity, so that diazotisation velocity is decreased by the smaller proportion of amine salt available".

The book is not well written, the meaning of the text often being difficult to find. The difficulty is enhanced by the use of unexplained abbreviations, for example, E.s.d. in the table on p. 5 and the arrow which appears in the statement "Griess obtained the azo-dye aniline → naphthylamine in 1864" on p. 77, while its significance is explained on p. 85. The contents of the book have been assembled with insufficient attention to detail and there are more accidental mistakes than one expects to find in a book that costs 90*s*.

G. Baddeley

COLLOIDS, OLD AND NEW

Organic Colloids

By Prof. Bruno Jirgensons. Pp. xiv+655. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1958.) 85*s.*

IN this book of 655 pages the author attempts a complete survey of colloid science, with boundaries extending inside biological fields, with the object of producing a text suitable for non-specialists and readable by "students and research workers who have had basic courses in physics and organic chemistry". The emphasis is on "basic facts and relationships rather than on theory" and the treatment is essentially non-mathematical.

The author is at pains to fit modern macromolecular chemistry into the framework of classical colloid science, with the result that one occasionally encounters unusual combinations of old and new. There is a wealth of readable information in this book, necessarily without great detail, and the author has succeeded in saying something about almost every major topic in his field—in itself no small achievement.

Unfortunately, however, the text is marred by occasional inaccurate or misleading statements and by an apparently arbitrary selection on the part of the author of the material included. The following are a few examples. On p. 37 we read "The life span of a free radical in the process of polymerization is estimated of the order of a few seconds only"—a misleading statement without further qualification. The polymerization of γ-methyl-L-glutamate N-carbonic anhydride in the presence of pyridine is not necessarily initiated by traces of water as implied on p. 45. The phenomenon described on pp. 316–17 and cited as an example of "replica polymerization" has, in fact, no connexion with the latter (see Waltcher, *J. Polymer Sci.*, 14, 411; 1954). The section on synthetic polyamino acids (Chapter 25, section 4) is particularly inadequate. The chain-growth of polyaminoacids in the Leuchs reaction is said to be promoted by the presence of a polyamino-acid (the observation being attributed to Waley and Watson), with the suggestion that this is a further instance of replica polymerization. This is quite untrue; the preformed polymers used by Waley and Watson simply function as initiators (in the systems studied) by virtue of their terminal base groups, as stated clearly by these investigators; no mysterious "orientation effects" are involved. The α polypeptide of D-glutamic acid is not the capsular substance of *Bacillus anthracis* as might be inferred from p. 428. The important fact, mainly responsible for the recent rapid growth in interest in synthetic polypeptides, that these polymers can exist in crystalline α and β forms is not even mentioned. Finally, the uninitiated reader, looking at p. 474 and Figs. 125 and 126, will be left wondering whether silk fibroin is, after all, a β protein. Defects of this kind detract considerably from the value of the book as an introduction to macromolecular chemistry.

The first 16 chapters (comprising Part 1, 280 pages) deal with fundamental principles and general methods of preparation and study, while the remaining 18 chapters (Part 2) deal with selected groups of organic colloids. The scope of this part is illustrated by the following selection of chapter headings: Macromolecular hydrocarbons: Cross-linked space polymers; Cellulose and similar polysaccharides; Globular proteins; Nucleic acids, nucleo proteins and viruses; Colloid phenomena in cells and tissues; Colloid-chemical characterization of biocolloids in disease; Micellar detergents, dyes and pigments.

The book is well produced and misprints are few.

C. H. Bamford

VIRUS AND VEGETABLE

Investigation of Virus Diseases of Brassica Crops

By Dr. L. Broadbent. (Agricultural Research Council Report Series, No. 14.) Pp. vii+94+8 plates. (Cambridge: At the University Press, 1957.) 15*s*. net.

BRASSICA crops are susceptible to two virus diseases, cabbage black ringspot and cauliflower mosaic, which, periodically, have caused great loss to the industry. The years 1948–50 saw more than usually severe outbreaks in crops of cauliflower and broccoli. In 1950, Dr. Broadbent, with the collaboration of many members of the National Agricultural Advisory Service and others, began to expand work already in progress at Rothamsted Experimental Station with the view of learning more about these diseases, especially those aspects relating to their control. Work continued for the next five years, and in "Investigation of Virus Diseases of Brassica Crops" it is reported in detail.

The contents of the book may be divided into two main parts, one dealing with response to infection and the other with spread of virus. The first of these includes a study of the response of a wide range of hosts including many different varieties of cauliflower, cabbage, and other brassicas, and the effect of factors such as strain of virus, weather conditions and manuring on symptoms. It also includes a useful list of plants susceptible to each virus. The other part of the book deals first with the process of transmission of the viruses, including the relative importance of different species of aphids in the natural spread of the diseases and, secondly, with their spread into and within the seedbed and crop. Appended is a short account of the two viruses transmitted by flea-beetle causing turnip yellow mosaic and turnip crinkle.

The recommendations for control which emerge from the study are similar to those advocated in the past. However, the experimental scrutiny to which they have been put should enable them to be applied with greater confidence and effectiveness. It is heartening to learn that commercial varieties of cauliflower differed both in the readiness with which they became infected and in the severity of the symptoms displayed after infection. This encourages the hope that varieties with increased resistance or tolerance may be bred for use in the future.

The inclusion of a large amount of experimental detail tends to slow the reader, but this is largely off-set by good lay-out. The production and most of the plates are excellent. Combining as it does original observation and reference to the published work of others, it will be of great service to those requiring an up-to-date and full account of the virus diseases of brassicas.

J. H. Hitchborn

AN IMPORTANT HERBARIUM

The Sloane Herbarium

An Annotated List of the *Horti Sicci* composing it; with Biographical Accounts of the Principal Contributors, based on Records compiled by the late James Britten. Revised and Edited by J. E. Dandy. Pp. 246+2 plates+96 facsimiles of handwritings. (London: British Museum (Natural History), 1958.) 147*s*.

AMONG the historical collections at the British Museum (Natural History), the Sloane Herbarium is one of the most important. A few years ago the director, Dr. G. R. (now Sir Gavin) de Beer, published a biography of Sir Hans Sloane, under the title "Sir Hans Sloane and the British Museum" (published for the Trustees of the British Museum by the Oxford University Press, 1953). Sloane is rightly regarded as the founder of the British Museum and his herbarium is probably the most extensive accumulation of botanical specimens of the seventeenth and early eighteenth centuries extant or ever made. The dried specimens forming the *Horti Sicci* are in bound volumes (*H.S.* 1 to 334), many one to a volume, but some bound together in twos or threes, five not present, one (*H.S.* 334) in two volumes, and eight with extra numbers giving a total of 265 volumes.

The late James Britten, who for thirty-eight years was an assistant in the Department of Botany at South Kensington, prepared an account of the Sloane Herbarium, which was unfinished at the time of his death and was not published. This account made, it is that the figures on some of them are somewhat overcrowded, and the lettering is at times too faint.

An interesting outcome of the investigations is the light thrown on the provenance of the unlocalized specimens, named and figured by Audouin and Savigny, which were collected during Napoleon's invasion of Egypt. The close agreement between them and the Indonesian material indicates that they came most probably from the Red Sea coast rather than the Mediterranean.

There are a few nomenclatorial surprises in the work, such as the demonstration of the priority of *Margaretta* Gray over the well-known *Tubucellaria* d'Orbigny, and of *Dakaria* Jullien over *Watersipora* Neviani. The replacement of *Catenicella* auctt. by *Vittaticella* Maplestone may also be regretted but is correct. In three other instances, however, Harmer, always hitherto a stickler for the sanctity of the International Rules of Zoological Nomenclature, strays from the path of virtue—his substitution of the type species of *Celleporaria* Lamouroux and *Schismopora* MacGillivray by others cannot be accepted, and his statements on the taxonomy of *Hippoporella* Canu are open to serious question.

These are small blemishes, however, in a volume which completes a remarkable life-time's work on the Polyzoa. Harmer, of whom there is a striking portrait in this last volume, carried out his extensive studies with a scrupulous regard for scientific accuracy; he expressed his observations and conclusions with a clarity and fullness that make them easy to comprehend and use. In the result, his *Siboga* Reports rank as the finest contribution to our knowledge of the Polyzoa since G. Busk's classic *Challenger* Report in 1884.

Finally, we must refer to the parts played by Dr. Anna B. Hastings and Dr. L. F. de Beaufort (the editor of the reports) in the present publication. Harmer had mostly completed his work when the Second World War broke out, and the printing of the plates had already started in Holland in 1940. By the end of the War, Harmer's failing health had stopped his further work, and at his request Dr. Hastings was entrusted with seeing the report through the press. It must have been no easy task, as the typescript was not as ready for publication as had been supposed. Nevertheless, with her wide knowledge of the group, she was able to co-ordinate and frequently check the text. At the same time, she studiously avoided modifying Sir Sidney's observations and opinions: although she has made several pertinent comments, they are all clearly indicated. For all this, the zoological world owes a great debt to Dr. Hastings, as well as to Dr. de Beaufort, who wisely decided after the War to carry on with this important publication.

GEOLOGICAL NOTIONS OF BERNARD PALISSY

The Admirable Discourses of Bernard Palissy.

Translated by Aurèle La Rocque. Pp. x+264. (Urbana, Ill.: University of Illinois Press, 1957.) 5.50 dollars.

THE phenomena of the Earth's crust attracted attention long before the foundations of geology were laid at the beginning of the nineteenth century, but though pregnant with possibilities, the early observations had little effect upon contemporary thought and never came together as parts of a developing theme. Even to-day they are usually cited as novel notions anticipating present-day knowledge.

For this reason, an English translation of the "Admirable Discourses" of Bernard Palissy, a book that is neither readily accessible, nor easy to read in its sixteenth-century French, is very welcome because his work in ceramics and enamel is better known than his contributions to geological thought. It shows us the working of the mind of one who, had he lived two centuries later, would have contributed towards the emergence of geology as a science, and although the limitations of his knowledge sometimes led him to conclusions that we now know to be wrong, in those in which he was right he showed perspicacity beyond that of his contemporaries.

In a short introduction, the translator summarizes the little that is known about Palissy's early life, reviews his later activities against the political and religious background of his time, and appraises his contributions in the field to which the book relates.

Palissy spent much of his time at Saintes, north of Bordeaux, and although by no means uneducated, had little formal training; what he had did not include Latin and Greek so that his opinions were not greatly influenced by classical and medieval writers. For some years after 1575 he gave lectures on natural history in Paris, but his unorthodox scientific views, added to his adoption of the reformed religion, led to periods of persecution and his ultimate death in the Bastille.

The breadth of the field he made his own is indicated by the title of the book which embodied the material of his lectures—"Discours Admirables, de la nature des eaux et fonteines, tant naturelles qu'artificielle, des metaux, des sels et salines, des pierres, des terres, du feu, etc.". It is written in the form of a dialogue between 'Practice' and 'Theory'. Practice (himself) instructs Theory, who puts the questions or challenges the answers. When Theory called him a great dolt for doubting the philosophers who argued that the water of springs was provided by the sea, he replied that if that were the case spring water would be salty (which it is not) and the sea would have to rise as high as the highest springs (which it does not). "Don't you know," he continued, "that the land is full of holes, cracks and abysses through which the water coming from the sea would come out on the plains before it could climb the mountains? Now fetch your Latin philosophers to give me a contrary argument that would be as easy to grasp as the one I put forward."

He regarded springs as being supplied by rain water that had percolated down through sandy material until it reached an impervious bottom that could hold it up, and he was the first to give a correct explanation of artesian wells. He denied that fossils were relics of the Biblical flood, but thought them to be the remains of animals that had lived where the fossils are found, from which it followed that there had once been water where there was now dry land. His knowledge was not extensive enough to enable him to follow the argument to its logical conclusion and to suggest that land and sea had changed places, and he explained the phenomenon by postulating lakes that had drained away.

He recognized that rocks were not formed all at the same time, described an auger with a hollow tube at has now been revised and edited by Mr. J. Dandy, the present keeper of botany, and, with an introduction by Mr. Spencer Savage, formerly librarian and assistant secretary to the Linnean Society of London, is printed by order of the Trustees of the British Museum.

In a preface, Mr. Dandy modestly refers to the amount of revision he had to undertake on Britten's manuscript. This involved a page-by-page examination of all the volumes, many additions to and modifications of the original text, and modernization of botanical and other names. He emphasizes that the book is not a catalogue of the specimens in the Sloane Herbarium but a guide to its contents with historical information about the collectors. To taxonomists the type-specimens present in the Herbarium are of greatest importance and a complete list of these has not yet been prepared.

Mr. Savage revised and arranged the manuscripts left by James Britten, selected the facsimiles of handwritings, of which 96 are reproduced, and prepared an introduction. In this he gives some interesting generalizations regarding the collections that make up the Sloane Herbarium. Specimens were obtained from as many sources as possible with the aim of accumulating more new and rare ones than anyone else. No serious attempt was made to determine the plants taxonomically and there was so little arrangement that Linnaeus, who saw the Sloane Herbarium on his visit to England in 1736, wrote that it was 'in complete disorder'. Later there were attempts to refer the specimens to Ray's "Historia Plantarum" by Sloane himself and by Dr. Johann Amman, who became his curator. Since the Sloane Herbarium is made up of specimens from many collectors and previous owners the correct attribution of handwritings is of great importance, and Savage did good service in identifying many of these. Further notes regarding the Sloane collection are contained in the few pages of general talk by Britten.

The main bulk of the volume consists of two parts: an annotated list of the *Horti Sicci* composing the Sloane Herbarium and biographical accounts of contributors, together with some information about their specimens. Among the more important collections in the *Horti Sicci* are those of Sloane himself made in Jamaica and on the voyage thither (1687–89); those of Bartram, Catesby, Courten, Cuninghame, Kaempfer, Kamel, Kiggelaer, Petiver, Plukenet, and Vernon. There are many collections of British plants, including some first records for the British flora, and plants from gardens of which those of Philip Miller from the garden of the Apothecaries' Company at Chelsea are probably outstanding in taxonomic importance, and those from the garden of the Duchess of Beaufort, at Badminton, Gloucestershire, and from Boerhaave, Leyden, are of considerable horticultural interest. While the plant specimens are not listed the countries of origin of many of the collections are given.

The second part is an alphabetical list of those persons whose collections (first- or second-hand) make up the Sloane Herbarium together with longer or shorter accounts of their lives and of their contributions to the Herbarium. There is much useful and interesting information for the botanical historian here and numerous bibliographical references are given. The usefulness of the book is increased by an index to geographical localities and another to botanical names. The facsimiles of handwritings, mentioned above, are well reproduced as plates at the end of the volume.

W. B. TURRILL

THE *SIBOGA* POLYZOA

The Polyzoa of the *Siboga* Expedition

By the late Sir Sidney F. Harmer. Part 4: Cheilostomata Ascophora, II (Ascophora, except Reteporidæ, with additions to Part 2, Anasca). (Monographie, 28*d*, Uitkomsten op Zoologisch, Botanisch, Oceanographisch en Geologisch Gebied verzameld in Nederlandsch Oost-Indië 1899–1900 aan boord H.M. *Siboga*. Uitgegeven door Dr. Max Weber en Prof. Dr. L. F. de Beaufort.) Pp. xv+641–1147+plates 42–74. 240 guilders.

When Sir Sidney Harmer died in 1950 he had published since 1885 a long series of papers on the Polyzoa, including three reports (1915, 1926 and 1934) on the Polyzoa collected on the *Siboga* Expedition. The present volume, by far the largest of the reports, completes his studies on those extensive collections. Apart from three and a half pages, it deals with the Ascophora. Harmer had intended to divide these into two divisions, the Ascophora Imperfecta and the Ascophora Vera, based on the nature of the compensation-sac. The distinction is an important one, but, although his typescript explicitly referred a few families to the former, it was not clear (for reasons given below) whether all the remaining genera were to be included in the Ascophora Vera or only the majority of them. These 'remaining genera' are divided among thirty families, with eleven others unplaced. Altogether, species belonging to 84 Ascophoran genera are described, and numerous other genera discussed. The systematics and synonymies of the genera and species are dealt with fully.

As is usual with Harmer's work, the Polyzoa were not studied only from that point of view, however. Careful and detailed analyses of the morphology of the zoaria of a number of species are also given—an outstanding example is that of *Siphonicytara formosa* Harmer, and those of the species of *Conescharellina* are also noteworthy.

Previous to the *Siboga* Expedition, very little was known of the Polyzoa of the East Indies, and nothing of their deep-water representatives there. Now, Harmer's work has revealed a rich and varied Polyzoan fauna, collected from the shore-line down to abyssal depths, though the majority come from less than 90 metres. Some of the species have wide bathymetric ranges, for example, *Celleporaria tridenticulata* (Busk) was found at depths from 0–397 metres, and *Agalmatozoum decussis* (Canu and Bassler), previously recorded from 249 fathoms, was found at depths between 535 and about 3,000 metres.

As was to be expected, the East Indian Polyzoa show many similarities to those of the Philippines, although they include numerous species not described from the latter area by Canu and Bassler in 1929. In his comparisons, Harmer not only made full use of a collection of Philippine Polyzoa which those authors had sent to the British Museum (Natural History), but also of others, such as the Haddon Collection from Torres Straits and, more particularly, the Thornely Indian Ocean Collections. As a consequence, we now have full and easily usable synonymies and descriptions of the Polyzoa of the Red Sea and Indian Ocean. These are amplified by a wealth of clear and beautiful figures, such as characterize all Harmer's works, figures all drawn by the author himself. If any criticism of the plates can be the tip and handles of different lengths for bringing up samples of soil from various depths, and observed that crystals assumed characteristic angular forms, just as it was "given to plants to keep a certain order, as you see that roses and gooseberries form prickly spines for their defence".

The interest of the "Discourses" lies not only in their revelation of what Palissy noted and inferred, but as much in what he failed to realize by reason of the limitations of his own observations and his lack of knowledge of what others had discovered in the same field.

F. J. North

QUANTUM MECHANICS

The Principles of Quantum Mechanics

By Prof. P. A. M. Dirac. Fourth edition. (International Series of Monographs on Physics.) Pp. xii+312. (Oxford: Clarendon Press; London: Oxford University Press, 1958.) 35*s*. net.

THIS is the fourth edition of a work too well known to require reviewing in detail. Dirac's "Quantum Mechanics" must surely still have its place on the shelves and in the heart of every serious student of quantum theory. For as long as the reviewer can remember it has been part of the scheme of things—quantum theory absolute as first conceived by the author and as no one but he could set it forth. What other subject possesses a text-book which combines in this way such definitive character and yet such dissimilarity in form from all other treatises on the subject? Here is Dirac's "Quantum Mechanics" and there Pauli's "Handbuchartikel", scarcely recognizable as dealing with the same subject and, as it were, illustrating the principle of complementarity; the serious student could not do better than study them side by side, as was the reviewer's good fortune to do in his student days.

For the second and third editions the author rewrote much of the text, but in doing so, did not fundamentally change the spirit of the work, even when in the third edition he introduced the entirely new *bra* and *ket* notation. In this present edition the main body of the book has undergone almost no change, but the concluding chapters on relativistic quantum theory have been rewritten and altered very profoundly. Curiously enough the theory of the Dirac electron as expounded by Dirac and the developments following it have always seemed to the reviewer to be the least satisfactory parts of the earlier editions of this book. Just because the relativistic theory itself has not arrived at the same state of conclusiveness as the rest of quantum theory, the characteristic Dirac style is inevitably less satisfying when dealing with it. It has also been apparent for some time now that the treatment of the interaction of the electron with the electromagnetic field given in the third edition, far from being definitive, showed Dirac to be turning away from the main stream of current thought on the subject.

This has now been recognized by the author, who admits that "a quantum electrodynamics which demands conservation of the number of charged particles is . . . out of touch with physical reality". The extensive modifications made in consequence are most welcome (as is also the minor change to the more usual sign convention for the Hamiltonian and the α-matrices). The student of the new edition, instead of being ultimately deflected from the main stream of modern research, is now guided to a point where this stream is just within sight. However, he is not cast adrift in its turbulent waters. True to his principles to the last, the author stops short of all considerations which cannot be developed with full logical consistency. Renormalization, for example, is not even named and only the last half page makes reference to what occupies so many quantum physicists to-day: "People have succeeded in setting up certain workable rules", says the author, but in spite of the success of these rules in interpreting experiments, he refrains from discussing them, pointing out (with full justification) that they "do not fit in with the logical foundations of quantum mechanics", and leaving it at that.

At first reading one may regret the omission of so much important matter, but on reflexion would one not agree that this is as it should be? Dirac stands for perfection and where perfection is not yet possible, let others take over.

N. Kemmer

COMPRESSIBLE FLOW IN HIGH-SPEED AERODYNAMICS

High-Speed Aerodynamics (Compressible Flow)

By Prof. Elie Carafoli. Pp. 702. (London and New York: Pergamon Press, 1957.) 100s. net.

THE book is a translation of a Roumanian publication entitled "Aerodinamica Vitezelor Mari", edited by Editura Academiei R.P.R., Bucharest, and follows an earlier book on incompressible flow published by the same author. The latter has been translated into German and Russian but not, so far as I know, into English. In this book on compressible flow, Prof. Carafoli attempts to give a comprehensive account of subsonic and supersonic aerodynamics and in fact states in the preface, "we have endeavoured to deal with some present-day problems relating to compressible fluids both in their theoretical aspect and more particularly in their application to current problems of aviation".

While the author has gone a long way towards achieving this objective, he has not, in my opinion, been entirely successful. The book is mainly mathematical and contains much useful theoretical information on one- and two-dimensional flows of perfect fluids, but other aspects are given inadequate treatment, particularly those for which theory is not fully developed. In consequence the book lacks balance, and pays more attention to solved problems than to a discussion of those which are difficult to treat theoretically. For example, it contains little of practical value on methods of estimating wing loading in subsonic flow, whereas the corresponding problem in supersonic flow is dealt with at much greater length. Even so, attention in the latter case is mainly given to delta wings, for which mathematical solutions exist. No mention is made of Evvard's method, and the problem of estimating loading on wings of general plan form is not covered as adequately as it might have been. Hypersonic flow is not considered, and the book concludes with a section on unsteady flow theory which is no more than a brief and elementary introduction to the subject.

Progress in aerodynamic research is so rapid nowadays that a book which is up to date when written is inevitably much out of date, through no fault of the author, by the time it is printed and issued. Most of the few references in the present book refer to work that was done before 1954. Although the book is lacking in some respects, particularly in the practical application of theory, it could be read with profit by any student of aerodynamics who is mainly interested in the mathematical solution of compressible flow problems. From the general reader's point of view, however, it could be greatly improved by the inclusion of more experimental data for comparison with theory, and fuller discussion of problems that are not amenable to theoretical treatment. An author's and a subject index would also make it more useful for reference purposes. W. P. JONES

NUCLEAR THEORY

Shell Theory of the Nucleus

By Prof. Eugene Feenberg. Second printing. (Investigations in Physics, 3.) Pp. xi + 211. (Princeton, N. J.: Princeton University Press; London: Oxford University Press, 1955.) 4 dollars.

THIS volume is the third production of the Princeton University Series "Investigations in Physics". When it was first published in 1955, the covers were of paper and the style of print was that of typewritten stencils, both features suggesting that serious effort had been devoted to keeping the price to a minimum. The actual cost was rather less than thirty shillings, which was impressively low for a specialized American text.

A second printing has now been made without any change in textual content, style or price. (Even typewriting errors are reproduced.) Unfortunately, between the two printings, the book has suffered the usual fate of expositions on topics in the front-line of research, and has become dated. Even when the book first appeared, it could not be said to provide an adequate discussion of all important branches of the subject-matter. This is much more true now as a result of the publication of many new papers on nuclear shell theory in the past three years. The book is still a good guide to certain classical aspects of shell theory, but there are a roughly equal number of topics which are scarcely mentioned. In particular, there is little mention of the modification of the theory that has been made necessary by the discovery that many nuclei are not spherical but egg-shaped (the strong-coupling version of the unified model of Bohr and Mottelson). No space is given to the work of Brueckner and others on the problem of why the shell theory failed to explain nuclear binding energies. Most surprising of all, only very brief reference is made to the work of Inglis and Elliott on the intermediate coupling version of the theory, which results in some of the most convincing and detailed agreement with experiment. Preliminary reports on these items appeared in 1953 and a great amount of work has since been published. It is regrettable that the production of the Princeton Series, although admirable in many ways, apparently lacks the flexibility necessary to enable a dated text to be revised.

The book opens with a survey of the evidence for shell structure in the nucleus, then presents the single particle model, and follows this by successive chapters on the comparison of the model with electromagnetic moments, electromagnetic transitions (isomeric states), and beta transitions. The latter chapters contain tables of data which are not complete in view of recent results but give a fair picture of the situation. The last chapters give discussions of particular shell-theory configurations and of collective vibrations of nuclei. In several places, nuclei lighter than neon are discussed in terms of *j–j* coupling, although it is well established that this is a very poor approach to such nuclei.

TRANSISTORS

An Introduction to Transistor Circuits

By E. H. Cooke-Yarborough. Pp. xii + 154. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1957. Published in collaboration with the United Kingdom Atomic Energy Authority.) 15*s*. net.

An Introduction to Junction Transistor Theory

By Dr. R. D. Middlebrook. Pp. xxiv + 296. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 68*s*. net.

Transistor Circuit Engineering

Edited by Richard F. Shea. Pp. xx + 468. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 96*s*. net.

UNTIL recently, little of the vast amount of information published about transistors had come by way of books, with the result that many newcomers to the transistor field have found the going somewhat heavy. Now, it appears that the drought is being followed by a deluge and it is interesting to see how three of the recent books help to produce a more balanced literature.

All three books are primarily concerned with the application of transistors, although Middlebrook's should also appeal to the designers of transistors. Cooke-Yarborough and Middlebrook intend their books as introductions, each author choosing an approach which is based on his own interests and experience. Shea and his co-authors, on the other hand, set out to give detailed guidance to the design of a wide range of transistor circuits.

After describing, with commendable brevity, how it works, Cooke-Yarborough considers the transistor as a circuit element. He discusses its use in various circuits, in each case carefully explaining what the transistor does, an approach which will help the reader when later he has to solve his own transistor problems. In view of Cooke-Yarborough's earlier contributions, it is not surprising that non-linear circuits take pride of place. Despite this limitation, the book should still appeal to both students and practising engineers who are looking for a readable introduction to transistor circuits. Some may find the unusual symbolism irksome, but the clarity of Cooke-Yarborough's writing should more than enable them to find the capacity for forgiveness.

Middlebrook's main interest centres around the transistor as a linear amplifier. However, the first section of the book deals with transistor physics, both qualitatively and quantitatively. This is followed by a section on electrical characteristics, leading to the derivation of equivalent networks for transistors. Much of the third, and final, section is taken up with a particular equivalent network. Engineers who specialize in the design of transistor linear amplifiers will find in this book a thorough theoretical background to the transistors themselves. Many others, including the designers of transistors, will find this a

THE WIENER-HOPF TECHNIQUE

B. NOBLE

Methods based on the Wiener-Hopf technique for the solution of partial differential equations

The methods described in this book solve certain boundary-value problems of practical importance involving partial differential equations. Mr. Noble takes the student from ordinary degree studies into the research field and provides the research worker with a comprehensive summary of what can be done by the technique at the present state of knowledge. Written for workers whose interests are primarily in applications of the theory rather than in the theory itself, the book can be read by anyone familiar with the Laplace transform, its complex inversion formula and integration in the complex plane. The first chapter will supplement the usual undergraduate course in complex-variable theory and familiarize the reader with the use of the Fourier transform in the complex plane.

In preparation

FOURTH NATIONAL SYMPOSIUM ON VACUUM TECHNOLOGY TRANSACTIONS 1957

Editorial Supervision *W. G. MATHIESON*

These annual volumes on vacuum technology are the only place where an up-to-date review of progress can be found. The present volume includes papers on the fundamental developments of vacuum technology and engineering, new methods and techniques for obtaining high vacuum, instrumentation, controls and other vacuum devices. The ever higher energies and power being sought by man and the probes into the physical nature of our universe emphasize the importance of high vacuum engineering and the great progress that is taking place.

PERCEPTION AND COMMUNICATION

D. E. BROADBENT

Applied Psychology Unit of the Medical Research Council, Cambridge

Recent experimental work within the field broadly known as "attention" is reviewed with the emphasis on hearing rather than vision. Considerable space is given to a re-examination of the problems usually handled by neo-Pavlovian theory and while some knowledge of current psychological theorising is desirable, it is not assumed that the reader is familiar with information theory or has any mathematical knowledge.

This is the first book in which problems in the study of hearing are considered from both a cybernetics viewpoint and from a detailed examination of the experimental literature, and it plays an important role in adding to our knowledge of, and stimulating further research in, the study of hearing.

OPERATIONAL RESEARCH IN PRACTICE

Edited by

MAX DAVIES and MICHEL VERHULST

Published for Agard

The papers and discussions in this volume were given at a NATO Conference held in Paris during 1957, designed to promote and guide the development of operational research in NATO countries. The book gives an account of what operational research can do and a unique and valuable feature is the fact that both papers and discussions tend to proceed from a military basis (which had its origin during World War II) to the civilian and industrial applications.

LEAK DETECTION

HEADS you find it . . .
TAILS you don't !

Don't waste time and money using inefficient and out-of-date search methods for locating leaks in vacuum systems. Leybold Vacuum Sales Ltd. offer you . . . free of cost (for the Greater London area) a leak detection service . . . fully equipped with qualified personnel and specialised instruments for locating leaks in vacuum systems. Take advantage of this service by 'phoning.

Phone GERRARD 9641

For those who prefer to have such leak detection equipment always at hand, Leybold can supply these specialised instruments.

New information booklet on TANTALUM · NIOBIUM & ZIRCONIUM now available

This new booklet gives full information on the uses of these metals, together with the dimensions of the various forms in which they can be supplied. The maximum and minimum sizes, together with normal tolerances, are also included. Useful data are given showing the properties of the metals, including their resistance to corrosion, together with details concerning the relation between weight and length for various diameters of rod and wire. A section is devoted to the illustration of types of corrosion-resistant chemical plant which can be supplied.

useful book, in which the subject matter has been well planned and ably presented.

Shea's book covers most kinds of transistor circuits, and is in many respects an enlarged and more advanced version of another book which he edited a few years ago. Written by a team of specialists, it naturally contains a wealth of practical information. However, it is not always up to date, a weakness that is inherent in a reference book that covers a rapidly developing subject. Nevertheless, it will be welcomed by many practising engineers, particularly by those whose work covers the design of a wide range of circuits. In addition to detailed studies of circuits, it contains a chapter describing how some of these can be fitted together to produce a practical equipment.

Without doubt each book fulfils a need and helps to bring a fascinating subject within closer reach of electrical engineers. D. D. JONES

DETACHMENT RELINQUISHED

Personal Knowledge

Towards a Post-Critical Philosophy. By Prof. Michael Polanyi. Pp. xiv+428. (London: Routledge and Kegan Paul, Ltd., 1958.) 42*s*. net.

A CHARACTERISTIC feature of the contemporary approach to science is that, both as a discipline and as a substantial part of knowledge, it is objective, and basically impersonal. These features are commonly considered to be virtues. For some time, and in several quarters, doubts have been cast upon this view: now in this monumental work Prof. M. Polanyi adopts a position completely rejecting the whole ideal of scientific detachment. There must be such a thing as the conception of knowing, and it is just this which he sets out to modify. Indeed, his title, "Personal Knowledge", demands some reconciliation, otherwise the two words appear contradictory. For his machinery, the author turns to *Gestalt* psychology. It is true, as he says, that scientists have shied at the philosophical implications of the theory: for himself he embraces them, prepared for the consequences. Naturally, these are likely to be more far-reaching in the biological sciences than in the domain of physics and mathematics. Otherwise expressed, the urge to detachment has done more harm in the former sphere: in the latter, at any event in recent years, formal impersonality has become somewhat disregarded. The late E. S. Russell (whose name, by the way, does not figure in the excellent index) was something of a pioneer in his "Directiveness of Organic Activities", and reached much the same conclusion, but by rather different paths.

This use of the *Gestalt* concept is vital, for, as is common knowledge, its outstanding principle is that of integration. Otherwise, Prof. Polanyi would have found himself inhibited from achieving what is perhaps the summit of his endeavour, namely, to link all purposive awareness to value. Axiological frustration may well be one of the deepest ills of our epoch; here at least is a system of methodology capable of resolving the paradox of increasing power with diminishing faith. The fact is that nobody but the author could possibly have written this book, or anything like it. The passionate element in the very act of knowing is not something subordinate; it is of the essence of creative ability. With it goes the coupling—more and more demanded as our mental process deepens—between the sciences and the humanities, if man is not to flounder in a bog, largely of his own making. Meanwhile, it is perhaps as well to face the essential difference between science and technology. Both need originality, which is therefore not a discriminant. What the scientist does is to probe more deeply into the nature of things than other people: the technologist, however, is quick to see how phenomena can be turned to practical ends, which involves the assessment of a host of factors entirely irrelevant to the scholar as such.

Under the general heading of "Commitment", several matters are discussed which reveal the quality of the author's mind, and the grasp which he has obtained over his subject. In particular, one may note the high state of stress which accompanies the solution of a major problem. It is only possible to experience this if one believes that the question has an answer: in the event of success, there is rejoicing in discovery and more rejoicing in accepting it as true. This state of affairs is akin to the late Prof. E. A. Milne's "logical pressure", which he described as a kind of pre-condition for great discovery. (The immediate condition is slightly different, and contains certain historical and personal elements which together may produce simultaneous effects, or a near-miss, as the case may be.)

Over and above all this comes the struggle to gain agreement that something fundamentally new is both valid and intellectually coercive. An example would be the non-Euclidian geometries of Bolyai, Lobatschevski and Riemann. Again (pp. 308–9), we are reminded how great are the responsibilities of commitment when a judge decides a novel case within the framework of the existing law. Perhaps it is not wholly an accident that several high wranglers have achieved distinction on the Bench: men who have been through the rigours of mathematical manipulation, but who have not lost sight of the artistry of logical processes.

The relation between the axioms discovered by Gödel and logical inference machines has a direct bearing upon the current problems of automation in general. The crux of the matter would appear to be the extent to which the rules of any art can be specified. But any skill or connoisseurship, which is unspecifiable, cannot be fed into a machine. It looks as if it is just this class of human properties which forms the entire basis of Prof. Polanyi's thesis, namely those generated by the mind in its passionate search for truth. It is in this sense that "the powers of the mind exceed those of a logical inference machine".

Towards the end, the author introduces his concept of a heuristic field, with its analogues of lines of force, which "should stand for *an access to an opportunity*. . . ." It is significant that the greatest artists of the Italian rennaissance recognized this almost intuitively, when (as X-radiography has revealed) they made tentative outlines, perhaps with a blunt instrument, to the limbs of their figures before committing themselves to the final form. In the same way, Prof. Polanyi has spent some nine years in his majestic 'groping' for the ultimate verities, and thus shares in the wisdom of the ages "as one that traceth". F. I. G. RAWLINS

Veterinary Protozoology

By U. F. Richardson and Dr. S. B. Kendall. Second edition, revised. Pp. xii+260. (Edinburgh and London: Oliver and Boyd, Ltd., 1957.) 22*s.* 6*d.*

ALTHOUGH protozoal infections of domestic animals are of the greatest economic importance, especially in tropical and warm countries, there are scarcely any reliable English text-books of protozoology covering this field to which students and practitioners of veterinary medicine can turn for information. As the first edition of the book under review, written by the senior author some ten years ago, suffered from a number of defects, it was hoped that the second edition, now produced by the joint efforts of two authors, would be considerably improved. The results are, however, somewhat disappointing, and the presentation of the subject-matter is uneven.

The general morphology and cytology of the protozoa, as well as their physiology, host-parasite relations and classification, are dealt with rather briefly in an introductory chapter, which is followed by six chapters on the flagellates, among which the trypanosomes rightly occupy a prominent place. Here it may be noted that the definition of certain inner structures (blepharoplast, basal granule, parabasal body and kinetoplast)—here, and in the introduction—are contradictory and confusing. A short chapter on *Histomonas* and entamoebae is followed by four chapters on the Sporozoa (especially coccidia and piroplasms). These are adequately dealt with, but more space could have been given to toxoplasmosis. A special chapter is allocated to ciliates (*Balantidium*) and an assembly of protists of uncertain systematic status, followed by chapters on chemotherapy and techniques.

In all sections, the description of the pathogenic parasites and their life-history is accompanied by an account of the diseases caused by them, and their treatment. These form the most valuable part of the book, whereas the description of some of the species of protozoa is not sufficiently accurate or clear for their differentiation. Furthermore, the parasitological diagnosis of some infections would have been facilitated by the provision of more and better figures, and by reference to the existing ones in the text.

C. A. HOARE

Nuclear Radiation in Food and Agriculture

Edited by Prof. W. Ralph Singleton. (The Geneva Series on the Peaceful Uses of Atomic Energy.) Pp. xii+379. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 64*s.*

THIS book is one volume of a series being published to cover various parts of the Geneva Conference on the Peaceful Uses of Atomic Energy. The volume under review is devoted mainly to those portions of the Conference which are concerned with food and agriculture. Each chapter of the book is a paper from the Conference and has therefore already been published by Columbia Press in the Proceedings of the Conference.

The editor—Prof. Singleton—has selected 28 papers for this book, from nearly 100 which were on appropriate subjects. The ones he has chosen are either reviews, such as "Use of radioisotopes in soil and fertiliser studies" by A. L. Dean, or specialist papers on important topics such as "Genetic erradication of the Screw-worm fly" by Bushland *et al.* In this way the editor has produced a book which should appeal to a wide range of readers.

The majority of the papers in the book refer to work with plants rather than animals. This editorial choice was made because the papers involving animals were mainly physiological in nature, rather than of general agricultural interest. There is, however, a section of six chapters on genetical and biological hazards of radiation, some of which are mainly relevant to humans. These latter papers could have been omitted since they are not primarily of agricultural interest and can be found elsewhere. It might then have been possible to have included other more relevant papers. Nevertheless, the book covers much important work. There are eight main sections dealing with nuclear radiation in fields as diverse as the use of radioisotopes; photosynthesis; plant physiology, pathology and cytology; soils and fertilizers; crop improvement; food sterilization; in addition to the subjects already mentioned.

A further feature is a list of relevant papers including those which were not selected for publication in the book. This adds greatly to its value.

LORNA J. LILLY

National Libraries of the World

Their History, Administration and Public Services. By Dr. Arundell Esdaile. Second edition, completely revised by F. J. Hill. Pp. xv+413+12 plates. (London: Library Association, 1957.) 44*s.*

THE second edition of Dr. Esdaile's book describes some thirty-two of the national libraries of the world, the growth of their stocks and the development of their services and the effect of the Second World War. Admirably presented and produced, it is representative rather than comprehensive, and the selection has been determined by such considerations as fame, historical interest or administrative significance, and also with a view to geographical distribution. The British Commonwealth is represented by the British Museum and the National Library of Canada, with short notes on the National Library of Scotland and the National Library of Wales, the National Library of the Commonwealth of Australia, Canberra, the South African Public Library, Cape Town, and the State Library, Pretoria, and the United States of America by the library of Congress. That list also indicates the key importance of the notes on the place of each library in its national system, though even here a note on the British Museum which does no more than refer to the National Central Library can scarcely be regarded as adequate. The value of the book to a general reader and to many librarians would be enormously enhanced if these notes could be expanded to include a brief account of the several national systems and the way in which needs of those concerned with the varied fields of science and technology as well as of the arts and humanities are served.

R. BRIGHTMAN

Extinct and Vanishing Birds of the World

By James C. Greenway, Jr. (Special Publication No. 13.) Pp. x+518. (New York: American Committee for International Wild Life Protection, 1958.) 5 dollars.

DR. GREENWAY has performed a most estimable service in completing this scholarly and painstaking analysis.

The large-scale exploitation of the landscape of countries colonized by the modern European has made disastrous inroads into native faunas. The physical removal of great areas of habitat (for example, forests and swamps) and the ravages of introduced rats and cats have been responsible, more often than direct commercial exploitation, pest-control and 'sport', for the decimation of many kinds of animals.

Yet it is gratifying to see from Dr. Greenway's data that the picture is not yet as bleak as one might have thought. For example, the early British settlers freely ravaged the faunas of North America, Australia and New Zealand—yet only one Australian, one New Zealand and two North American 'full' species are known certainly to have disappeared, and only three more species are thought probably to have become extinct in those countries.

Of the thousands of species of modern birds, only 44 are known to have vanished, and a mere 12 probably have done so, although hundreds have become relatively rare and may be in danger. Of those that have gone, almost all were island forms. No less than 12 species—more than one-quarter of total extinctions—have disappeared from islands of the Central and Western Pacific alone. In certain cases at least, the chief factors responsible seem to be the impact of imported eutherians (particularly rats) on highly specialized island (often ground-nesting) natives.

The ecologist and evolutionist, as well as the conservationist, will find a great deal to interest him in this book; and Dr. Greenway is much to be congratulated on its production. A. J. Marshall

Georgia Birds

By Thomas D. Burleigh. Pp. xxx+746+48 plates. (Norman, Oklahoma: University of Oklahoma Press, 1958.) 12.50 dollars.

THIS large and handsome volume, published in co-operation with the U.S. Fish and Wildlife Service, is written and illustrated by men who have worked in the field in Georgia. It keeps commendably to the proper purpose of an area study, without attempting to be also a text-book or field-guide for local ornithologists. Thus, the main information for each species relates to its distribution or occurrence in the State, and to its habits as observable there, with a little background on general distribution and on recognition. There are contributed chapters on the history of ornithology in Georgia and on the physiography of the State. The fine colour-plates by G. M. Sutton depict characteristic species in their Georgian habitats; the photographs are primarily of environmental interest; and there are several distribution maps. Landsborough Thomson

British Herbaria

An Index to the Location of Herbaria of British Vascular Plants with Biographical Reference to Their Collectors. Compiled by D. H. Kent, with the assistance of E. B. Bangerter and J. E. Lousley. Pp. 101. (London: The Botanical Society of the British Isles, c/o Dept. of Botany, British Museum (Natural History), 1957.) 20*s*.

THE native British flora, so far as vascular plants are concerned, is relatively poor in number of species but is of particular interest from the geographical position of the British Isles on the north-western margin of Eurasia and because of the diverse ecological conditions within them. Many of the professional and amateur botanists who have studied British plants accumulated herbaria, and these are in many different institutions or in possession of individuals. To trace the whereabouts of some and to ascertain their value is not always easy, and the account compiled by Mr. D. H. Kent, with the assistance of others, will be useful to many who are making detailed researches on various aspects of the British flora. The list of universities, museums, and other institutions possessing herbaria of or with British plants is a long one. It is hoped that proper attention is given to the continued preservation of the specimens. The alphabetical index to collectors is "to indicate where material of individual collectors is represented, and often this is to be found in several herbaria". Obviously it is scarcely possible to compile a complete index of this kind and a great deal of dependence was placed on replies from those in charge of museums and other institutions. Useful information as to size of collections, dates of collectors, etc., is given under many of the names. There are, however, a great many gaps and it may be that the present publication will result in these being largely filled for a new edition. W. B. Turrill

Commutative Algebra

Vol. 1. By Prof. Oscar Zariski and Prof. Pierre Samuel, with the co-operation of I. S. Cohen. (The University Series in Higher Mathematics.) Pp. xi+329. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 52*s*. 6*d*.

THE present book makes its appearance after two decades of intensive research, in which the authors themselves have played a leading part. It will be of great value to graduate students and research workers who wish to specialize in this branch of mathematics, for it is the only connected account of the subject. After a chapter of basic definitions and concepts there is a polished account of the theory. This proceeds via field theory and the theory of ideals and modules to the properties of Noetherian rings. The ideal structure of such rings is thoroughly explored. The last chapter is concerned with Dedekind domains and classical ideal theory. Examples illustrating the theory are given in places. But the reader may find the account rather concentrated. If he asks why certain topics are introduced he will find no answer, for it is hidden in the geometric background to the whole theory and there is no hint of this except in the preface, where we are promised the motivation in the second volume. A surprising feature is the apparently complete lack of any references, either to other books or to original papers. It will be difficult for the reader to link the work with the related literature unless he is under expert guidance.

Commutative algebra began as a branch of abstract algebra in Germany and remained a child until the late thirties. Now it is a towering giant (hence this first of a two-volume work), existing in its own right. One questions whether the subject can expect to attain a position of near immortality, at the side of other branches of 'permanent' mathematics. It is true to say that it only grew because the parlous state of the theory of algebraic geometry seemed to point to the need for a new branch of algebra. Now we have it. But on the whole it has not yet done the job of work for which it was introduced. Nowhere in this first volume is there any indication of the motivation behind the development and the reader or prospective reader may, in looking for the purpose, be disappointed and close the book. It is to be hoped that the book has a better reception than this, but the reviewer has his doubts. L. S. Goddard

ROTATION OF ARTIFICIAL EARTH SATELLITES

By Prof. R. N. BRACEWELL and O. K. GARRIOTT

Radio Propagation Laboratory, Stanford University, California

A MARKED feature of the signals received from *Sputnik* 1 was the deep, regular fading having a semi-period of about 4 sec. Because of the persistence of this effect from day to day, and because it occurred on both the 20 and the 40 Mc./s. transmission, it seemed likely to be due to free motion of the satellite about its centroid. Simultaneous records exhibiting agreement are shown in Fig. 1. It is true that such simple behaviour was not invariably recorded (Fig. 2); however, if different aerials, or combinations of aerials, were used at the different frequencies, then mechanical rotation of the satellite could modulate the two transmissions in different ways; and further complications could be introduced by the rapidly changing aspect of the satellite and by propagation phenomena. The modulation under discussion is probably ascribable to mechanical rotation, but in any case it is clear that deep fading is to be expected and that it is an embarrassment for telemetry, radio position finding and ionospheric investigations. For example, in Fig. 3, the more rapid fluctuations on 20 Mc./s. contain information about ionospheric ionization[1], but some of the useful detail is obscured by the deep motional fading; and in Fig. 2 the ionospheric phenomenon is entangled with motional effects.

Evidently it is important to know about the state of rotation of satellites, and here means will be considered whereby rotational effects may be eliminated. Fig. 4, which shows a recent field-strength record on *Sputnik* 3, suggests that the problem may already be solved.

Consider a pencil-shaped satellite, such as *Explorer* 1, which is launched in a state of rotation about its longitudinal axis. At the moment of *Brennschluss* of the final rocket of the final cluster, let the instantaneous axis of rotation make a small angle α with the axis of symmetry of the satellite. Then the angular momentum vector $\vec{h}$ will be coplanar with the axis of symmetry and the angular velocity vector $\vec{\omega}$, making an angle β with the latter (Fig. 5). The angle β will depend on I and J, the axial and transverse moments of inertia, as follows:

$$\tan(\alpha + \beta) = \frac{\tan \alpha}{m} \qquad (1)$$

where $m = I/J$. For a very long and thin satellite not spinning true ($\tan \alpha \gg m$), the angular momentum vector will be almost perpendicular to the rod. (That this is so is evident from the instantaneous motions of the nose and tail, perpendicular to the paper (Fig. 5), in opposite directions.) For example, launching a homogeneous cylinder 6 ft. long and 6 in. in diameter, only 2° off true, will displace the angular momentum 74°.

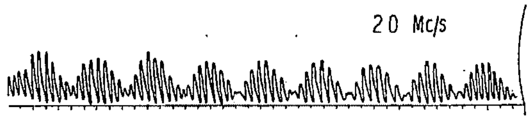
Fig. 2. Some anomalous observations on 20 and 40 Mc./s.



1957, October 9d. 15h. 13m. U.T.

Fig. 3. Rapid fluctuations associated with ionospheric ionization when the satellite passed over Stanford at great height

The ensuing force-free motion, or Poinsot motion, consists of an axial spin $n = \omega \sin \beta \operatorname{cosec}(\alpha + \beta)$ about the axis of symmetry superimposed on a slewing motion about the invariable line (the direction of total angular momentum) with an angular velocity $\Omega = \omega \sin \alpha \operatorname{cosec}(\alpha + \beta)$. To a rough approximation in the present special case:

$$n \simeq -\omega \cos \alpha$$

and

$$\Omega \simeq \omega \sin \alpha$$

This motion can be visualized as the rolling of a cone of semi-vertical angle α fixed to the satellite, on a fixed cone of semi-vertical angle β.

Thus, in addition to spinning with an angular velocity just below the rate imparted intentionally, the rod would execute a tumbling, waltzing or screwing motion, depending on the orientation of the invariable line to the direction of flight; and since this orientation changes it might waltz overhead at one place and proceed overhead like a propeller at another a quarter of a period later.

Undesirable as this is, both the rate at which it occurs, and the direction of the invariable line, may be set by accidental circumstances of launching not known in advance. It is now very interesting to draw a contrast with the much more favourable phenomena exhibited by a disk.

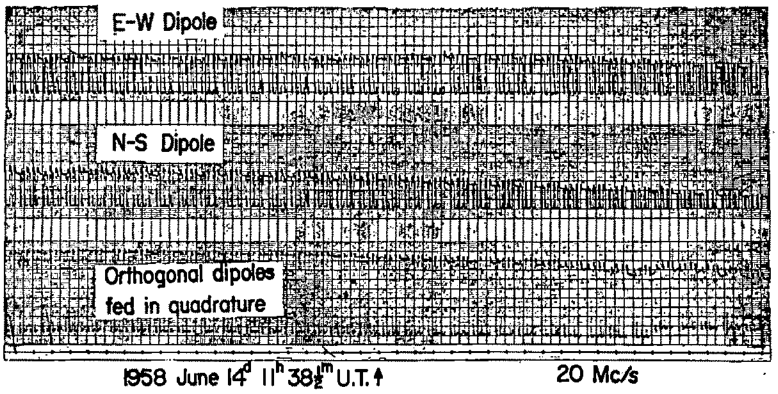


Fig. 4. Field strength record of *Sputnik* 3 which shows Morse-type modulation but which is free from pronounced rotational modulation, thus simplifying the study of interesting effects which shed light on the ionosphere

Let a disk be launched with an angular velocity $\vec{\omega}$ which by accident departs by an angle α from the axis of symmetry. Then the angular momentum $\vec{h}$ falls midway between this axis and $\vec{\omega}$, as may be deduced from equation (1) by putting $m \simeq 2$ (Fig. 6). The disk spins about its axis of symmetry with an angular velocity $n = (m - 1)\ \omega \cos \alpha$ and rocks about the invariable line with an angular velocity $\Omega = \omega \sin \alpha \operatorname{cosec} (\alpha + \beta)$, as before, but in this case the approximations for small α are:

$$n \simeq \omega \cos \alpha$$
$$\Omega \simeq 2\omega$$

Small errors thus produce small effects.

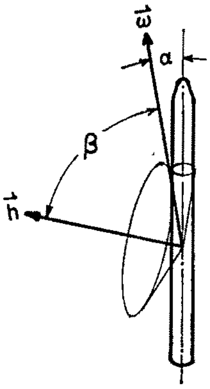

Fig. 5. Relationship of angular momentum $\vec{h}$ to a rod-shaped satellite

If a pair of transmitting dipoles, excited in quadrature, are placed orthogonally in the equatorial plane of a small satellite rotating precisely about its axis of symmetry (Fig. 7), clearly no modulation of signal level would be noticed at any place on the ground (other than small effects due to modification of the dipole radiation pattern by the satellite body). There would simply be a frequency shift equal to the number of revolutions per second. Such an antenna is therefore basically good for counteracting the effect of rotation on field strength and has been described in *Radio*[2]. If now the angle α is not quite zero, then in the case of a disk an observer not near the nulls of the radiation pattern will notice shallow amplitude modulation the rate of which is identifiable as twice the spin frequency. By contrast, the signal from the rod will be deeply modulated, at a rate not necessarily known in advance.

A disk-like satellite ($m \simeq 2$) thus has advantages. It is not necessary that the appearance should be disk-like, only that m be greater than 1. For example, *Sputnik* 3, a conical shell containing batteries fixed in its base[3], may well be disk-like as regards its moments of inertia.

Very interesting questions now arise as to whether the rocking or slewing motions may be suppressed, following the launching. Evidently, one way would be to operate suitable auxiliary rockets. Suppose, however, that the satellite contains viscous fluid or a vibration damper roughly tuned to the rocking frequency, which converts kinetic energy of rotation to heat. Then it can be seen, by bearing in mind the invariance of $\vec{h}$, that in the case of a disk the rocking will be damped out, and that the final angular velocity ω_2 will be given by

$$\omega_2 = \omega\left(\cos^2 \alpha + \frac{\sin^2 \alpha}{m^2}\right)^{\frac{1}{2}}$$

This will leave the angular momentum unchanged but will mean a loss of energy of $\frac{1}{2}J(1 - m^{-1})\ \omega^2 \sin^2\alpha$, or approximately half the energy associated with the rocking motion. In the case of a rod, the spin will be damped out, and the rod will be left slewing exactly in a plane with a final slewing velocity Ω which is unchanged:

$$\Omega = \omega \sin \alpha \operatorname{cosec} (\alpha + \beta) = \omega\ (\sin^2\alpha + m^2\cos^2\alpha)^{\frac{1}{2}}$$

which may be very different from ω. The loss of energy is $\frac{1}{2}\, I\, n^2/(1 - m)$, which is of the same order of magnitude as the spin energy. The possibility of stabilizing a disk by dissipation is another advantage in favour of this shape. Using a vibration damper of quality factor Q capable of storing one Nth of the

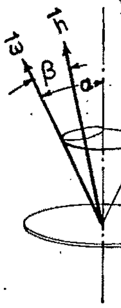

Fig. 6. Angular momentum and angular velocity of a disk-shaped satellite

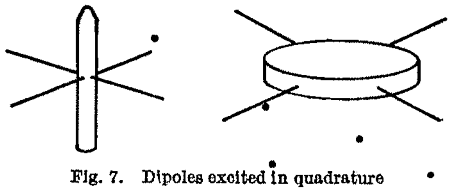

Fig. 7. Dipoles excited in quadrature

energy of the rocking motion, the damping time constant would be QN spin periods, which could readily be made a very small fraction indeed of a satellite's life.

This satisfactory result leaves only the question of also removing the spin rotation, which will, of course, be necessary in experiments requiring instruments to be pointed at celestial or terrestrial objects. Here it appears that the removal of angular momentum would suffice. For example, one might speed up an internal flywheel until the satellite body came to rest, and eject the flywheel together with all the angular momentum.

However, any method of increasing the moment of inertia about the axis of rotation would help. One might re-arrange the contents. Now it would not be necessary to reduce the satellite exactly to rest; for the purpose of observation from the ground one could accept a small rotation during the few minutes that the satellite was above the horizon of a given point, and the same applies to many celestial observations. By feeding out, under centrifugal force, a small mass in the form of a very long fine thread of strong material, the moment of inertia could be increased by a substantial factor and the spin velocity accordingly reduced.

The spontaneous observations of *Sputniks* 1 and 2 were participated in by D. Annett, K. C. Yeh and D. Pratt, members of the Radio Propagation Laboratory, Stanford University, under the direction of Prof. O. G. Villard, jun. Work on *Sputnik* 3 is supported by a grant from the U.S. National Committee of the International Geophysical Year. We are also indebted for stimulating discussion to participants in the Radio Propagation Seminar, which concentrated on satellites in the autumn and winter quarters, especially to Dr. A. T. Waterman, jun., and Mr. J. Fontana.

SIZE AND SHAPE CHANGES OF POLYELECTROLYTES: CONVERSION OF CHEMICAL INTO MECHANICAL ENERGY

CONTINUING earlier seminars[1] on polymer science in the Chemistry Department of University College, London, six lectures on size and shape changes of polyelectrolytes and on conversion of chemical into mechanical energy were given on April 14.

Prof. W. Kuhn (Basle) talked on the transformation of chemical energy into mechanical energy by high polymer systems made from vinyl alcohol and allyl alloxan, the alloxan component of which can be catalytically hydrogenated to a dialuric acid component. Slightly cross-linked filaments, containing this copolymer, swollen in dilute acetate buffer contract on hydrogenation and expand on oxidation, due to swelling and deswelling, produced by an increase of solubility in passing from the sodium salt of dialuric acid to alloxan. Thus, mechanical energy is produced from chemical energy arising from the oxidation-reduction process[2, 3]. In a previously described system, the chemical energy of neutralization had been transformed into mechanical energy with the use of filaments containing polyvinyl alcohol and polacrylic acid[4], dilation and contraction being brought about by pH changes. In these systems the length changes were accompanied by changes of the lateral dimension. A third system containing alternating layers A and B has been prepared, wherein length changes, exceeding 100 per cent, occur, without alteration of the fibre diameter[3]. A is prepared from heated cross-linked polyvinyl alcohol, and B is prepared from equal parts of polyvinyl alcohol and polacrylic acid also cross-linked by heating. The sandwiched layers A and B, moistened with polyvinyl alcohol, are dried, heated, brought into equilibrium with water and cut into strips. These contract and dilate respectively on the addition of acid and alkali; the cross-linked A-layers permit only a one-dimensional change of the B-layers and thus prevent a change of the lateral fibre dimension. In the dilated system the one-dimensional swelling of the B-layers is accompanied by optical birefringence. Swelling and birefringence disappear on the addition of acid. The volume change of these filaments during contraction or dilation is less than in the three-dimensional swelling and contraction; and the tensile strength of the filaments is maintained if the cross-section remains unaltered. The magnitude of the birefringence and the unidirectional swelling is in accordance with the requirements of the theory of polymer networks[5]. The stretching of the system involves a dilution of the B-layers owing to water uptake. An investigation of the Donnan-equilibrium between the interior of the B-layers and the outside shows that the stretching of the filaments produces an increase of pH in the outside medium. In the presence of a small quantity of sodium chloride the pH change is approximately proportional to the elongation of the B-layers. This pH change is such that the osmotic work required to stretch the B-layers chemically from L_1 to L_2 by increasing the degree of ionization from α_1 to α_2, and subsequently to return at constant lengths L_2 from α_2 to α_1, is equal to the mechanical energy required to stretch the B-layers mechanically at constant value α_1 from L_1 to L_2.

In the discussion, Prof. E. D. Hughes (London) asked whether the rate of the swelling and deswelling reactions is sufficiently large to make it feasible that processes of this kind are responsible for muscular activity. Prof. Kuhn replied that in his systems the rate appears to be diffusion controlled and depends on the fibre diameter. R. E. Cooper (London) referred to a paper by Hill[6], which shows that muscular activity can be so fast that diffusion from the surface of a fibre to its core cannot be rate-determining. If, however, in a twitch the outer region of the fibre were involved (for example, one half of the fibre diameter) then the rate of diffusion is fast enough to account for the observed rate of fibre contraction. In this connexion, Cooper referred to experiments[7] which showed that the length, the birefringence and the elasticity of fully swollen polyelectrolyte fibres can be markedly altered, at constant *p*H, by stoichiometrically well-defined cation exchange reactions.

Prof. J. A. V. Butler[7a] (London) gave a lecture on effects of salts on configuration of polyelectrolytes in which the electrolyte groups are ionized to a considerable extent. Two classes of linear polymers were considered : (*a*) those with flexible chains ; (*b*) those consisting of stiff chains. The configuration as deduced from their viscous behaviour in solution was discussed especially with reference to the effects of concentration and added salts. These polyelectrolytes are very sensitive to added ions, but there are marked differences, in that in (*a*) the effect of ions on the shape of the particle is the predominating factor, while with (*b*) the effect of added ions is principally on the interaction between particles. The behaviour of gels formed from these polyelectrolytes by the introduction of cross-links was discussed.

R. E. Cooper (London) lectured on polymerization of polyelectrolytes by magnesium ions[8]. Alginic acid (poly-*d*-mannuric acid) can be converted into water-soluble potassium, sodium and magnesium salts of well-defined stoichiometric composition. After special purification procedures the weight-average molecular weight of the potassium and sodium salt is below 3×10^5, while that of the magnesium salt is between 10^6 and 10^8. The hydrodynamic and other properties of these polyelectrolytes show that the increase of molecular weight does not give rise to a corresponding increase of molecular volume. It is concluded that the replacement of a monofunctional by a bifunctional counter ion gives rise, at constant *p*H, to a polymerization reaction in which a relatively small polyelectrolyte ion is converted into a larger, but much more compact, species. The effect is explained by the assumption that bivalent magnesium counter ions combine with the carboxyl and hydroxyl groups of the poly-acid to form inter- and intra-molecular bridges. The former are responsible for the large molecular weight, while the latter are responsible for the more compact configuration. Monovalent sodium or potassium counter ions, on the other hand, are not capable of producing cross-links.

In the discussion, Dr. H. Morawetz (Brooklyn) said that his work indicated the role of inter- and intra-molecular cross-links. In his systems molecular aggregation could be followed osmometrically, while group association was obtained from spectroscopy[9]. In studying the interactions with copper[10], the tendency of counter ions to associate with several groups attached to the same polymer could be clearly demonstrated.

According to Cooper and Wassermann[8], the properties of magnesium alginate depend on the sequence of operations in the preparation. Normally, the formation of magnesium chelates with carboxylic acids is rapidly reversible, and Cooper and Wassermann's results must be due to the co-operative effect of many complexes in a molecular aggregate. It has been observed that some polyvinyl chloride solutions attain their equilibrium state rather slowly ; and similar effects were noted by Boetger and Doty[11] in gelatine solutions.

Dr. H. E. Huxley (London) talked on structural changes during contraction of striated muscle[12]. The contractile material of striated muscle is composed of longitudinal protein filaments. There are two types of filament present, one type having a diameter (in frog and rabbit muscle) of about 100 A. and the other about 50 A. The thicker filaments are approximately $1 \cdot 5$ mμ long and contain actin. Filaments of each type are arranged in a succession of discrete arrays which overlap with arrays of the other type of filament, the two types of array occurring alternately along the length of the filaments and producing a band-pattern. During contraction and stretch the two arrays slide in or out of each other without any perceptible change in the length of the filaments of which they are composed. This seems to be brought about by cross-bridges between adjacent thin and thick filaments, and which correspond to the sites of actin myosin interaction. The cross-connexions occur at quite short intervals. The process by which chemical energy is transformed into mechanical work does not seem to be associated with appreciable changes in the length of the filaments.

Commenting on this lecture, Prof. W. T. Astbury (Leeds) referred to work[13,14] which shows that the X-ray diagram of dry skeletal muscle is effectively the sum of the diagrams of myosin and *F*-action ; and he pointed out that it is difficult at the moment to make the further desirable co-ordination with Huxley's electron microscope findings on what happens during contraction and stretch. Two other fine-structural lines of approach, however, are beginning to run together rather promisingly. In the first place, the concept of muscular contraction as a special manifestation, in myosin, of the property of supercontraction[15], and of the close association of the latter with the cross-β diagram[16], has lately been revitalized by the discovery of natural cross-β forms in bacterial flagella[14] and the egg-stalk of *Chrysopa*[17]. For these and other reasons[18], especially the configurational analogy between the polypeptide chains in the egg-stalk and basal pedestal of *Chrysopa* and the polyethylene chains in the astonishing crystals investigated by Keller[19], there can be little doubt now that the polypeptide chains in myosin, normally in the α-configuration, cannot merely be pulled out reversibly but can be contracted reversibly into a transversely folded configuration. In the second place, there is the recent demonstration by Doty and his collaborators[20] that the make-up of orthodox globular proteins, too, can consist in part of α-helices and that, moreover, the proportions of these can be reversibly varied to some extent. It follows in principle that there must be reversible changes in shape, when protein corpuscles form linear or other aggregates, with their neighbours. This provides the last decisive step in resolving the paradox between the long-range contractile fibre as a straightforward 'molecular yarn' and as a chain of corpuscles[18]. By virtue of these now established intra-corpuscular configurational changes, shortening of the latter can take place either directly or, more generally, by spiralization. Szent-Györgyi's discovery[21] that, by appropriate urea treatment, it is possible to dissociate myosin into small corpuscular units ('protomyosins') thus becomes not too difficult after all to reconcile with the classical X-ray point of view, and it is consistent also with the inference that bacterial flagella are of the nature of monomolecular muscles[14], and with the ultimate corpuscular construction of algal flagella[14], but unfortunately no approach along lines such as these seems compatible with Huxley's conclusions from electron microscope studies.

Dr. D. R. Wilkie[21a] (London) gave an account of the relationship between thermodynamics and the interpretation of muscle heat measurements. Active muscles produce a relatively large amount of heat, both during activity and during recovery; and the heat production is linked in some way to the mechanical change during contraction. Some of the chemical processes taking place in the muscle have been identified, and several of them are associated with large entropy changes. This introduces a serious uncertainty into the interpretation of the heat measurements.

C. A. Vernon (London) talked about the concept of phosphate bond energy[22]. The term 'high-energy phosphate bond' was first introduced by Lipmann[23] and had reference to the fact that the standard free energy of hydrolysis of adenosine triphosphate (ATP), which is said to possess a high-energy phosphate bond, is considerably higher than that of most simple orthophosphate esters.

Lipmann's concept has, however, led to considerable confusion and readily gives rise to pseudo-explanations concerning the role of adenosine triphosphate in biological processes. The quantities which provide the experimental basis for the high-energy phosphate bond concept are not bond energies, but standard free energy changes. As such they may may be used to calculate equilibrium constants, or to specify maximum work at unit activities. They do not provide explanations for the role of particular phosphate esters and are better not described by a highly misleading terminology.

ARCHITECTURE OF A PROTEIN MOLECULE*

By Dr. J. C. KENDREW

NEARLY all the molecules most characteristic of living matter are very large ones, containing hundreds or thousands of atoms; proteins, fats, carbohydrates and nucleic acids are typical examples. Living organisms nearly always have well-defined size and morphology, and it is not surprising that they should be built up from units which are themselves large and complicated; furthermore, the subtlety of the chemical reactions carried out by cells demands a corresponding complexity in the molecules which mediate them.

Among these biological macromolecules the proteins are paramount. Some proteins are used as structural components, for example, the long filamentous protein molecules of bone, of tendon, of hair, of skin; others compose the muscle fibres which convert chemical energy derived from food into the mechanical energy of a moving limb. Another kind of protein molecule are the so-called enzymes, the essential catalysts which control the rate and determine the ordered sequence of the chemical reactions enabling each living cell to play its proper part in the complex economy of the organism, in a manner quite beyond the reach of the chemist in his laboratory. The enzymes are perhaps the most interesting of all types of protein, and they are members of the class known as globular proteins, so named because their molecules are nearly spherical.

Large molecules found in living organisms are generally built up by the combination of a great number of small molecules of a few standard types. For example, nucleic acid molecules are made of only four types of standard part—the nucleotides—arranged in linear sequence along a chain, the difference between individual nucleic acids residing in the difference of order of the units, just as the meaning of a message in the Morse code is conveyed by its sequence of dots and dashes. In proteins the standard parts are called amino-acids; and although hundreds or even thousands of amino-acids, arranged linearly in chains, may be contained in a single protein molecule, these amino-acids are of only twenty different kinds. In the proteins the analogy is to written language rather than to the Morse code; we may think that they differ in behaviour in consequence of their differing amino-acid sequences in much the same way as the meaning of a sentence depends on the order of the letters of which it is composed. Each kind of amino-acid consists of the same standard 'link' (the chemical group $NH_2.\overset{|}{CH}.COOH$) attached to a 'side-chain' characteristic of the particular amino-acid. When joined together the links form the so-called backbone (or main chain), from which project side-chains of twenty different kinds; the whole is called a polypeptide chain.

---

* Based on an Evening Discourse delivered at the Royal Institution on May 21.

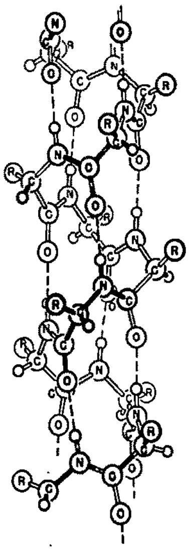

Fig. 1. The α-helix of Pauling and Corey. The side-chains of the amino-acids are all denoted by *R*

The actual sequence of the amino-acids in a protein was first determined by Sanger in the case of insulin. Sanger showed that every insulin molecule from a given species of animal contained the same fifty-one amino-acid residues arranged in the same order, and that the insulins of different species were nearly identical, differing by only one or two amino-acids in the whole molecule. In myoglobin, the protein which forms the subject of this article, there are more than 2,500 atoms, comprising 153 amino-acids linked together in a single chain. The amino-acid sequence of a protein is called its primary structure, and its determination for insulin was a great triumph of structural chemistry. But it is not the whole story: since the globular proteins are nearly spherical the amino-acid chains of which they are composed must be folded and re-folded like a ball of string. Furthermore, many proteins form very perfect crystals, which means that their molecules must be identical in shape as well as in amino-acid sequence, otherwise they could not pack together in the highly regular manner which a crystalline structure implies. We must therefore address ourselves to the question how the amino-acid chain in a protein is folded—for it is evident that the chemical behaviour of the complete molecule will depend on the spatial relationships of nearby amino-acids in the folded structure.

In 1951 Pauling and Corey showed that in some of the filamentous proteins of hair and skin and wool the polypeptide chain is arranged in the form of a regular helix, known as the α-helix (see Fig. 1); this is the so-called secondary structure of these proteins, and its presence is revealed by the X-ray pattern of the fibre, first studied in detail by Astbury in 1933. The α-helix has been shown to be present in many protein fibres, and there is suggestive evidence (though as yet no proof) that it also exists in globular protein molecules. By its nature, however, the α-helix is rigid and straight; a molecule made up of the 153 amino-acids in myoglobin, all in the form of a single α-helix, would be twenty times as long as it was wide, whereas, in fact, myoglobin is nearly spherical. It follows that there must be a yet higher category of fold—a tertiary structure—to bend the helix within the compass of a spherical molecule. Even this does not exhaust the complexities of protein molecules, for they often contain, in addition to amino-acids, some other type of chemical group, the so-called prosthetic group. Myoglobin contains such a group, a flat symmetrical arrangement of atoms with a single iron atom at its centre, known as the hæm group: it confers a red colour on myoglobin. When associated with the protein the hæm group has the property of combining reversibly with a molecule of oxygen; and indeed the function of myoglobin is to act as a temporary store of oxygen in the muscle cells, just as that of hæmoglobin (which also contains hæm groups) is to transport oxygen in the blood stream. Diving animals such as whales, seals and penguins need to store oxygen for long periods while they are under water, and accordingly contain large amounts of myoglobin so that their meat is very dark red; thus the studies of myoglobin about to be described were done with material derived from the sperm whale.

The only way of finding out the spatial arrangement of the atoms in a complex molecule is by studying the X-ray diffraction pattern of its crystals. The first structure so to be determined was that of sodium chloride. This molecule contains only two sorts of atom, and since 1913, when its structure was worked out by Sir Lawrence Bragg, the method has developed far, its most recent triumph being the determination of the complete structure of vitamin B_{12} by Dr. Dorothy Hodgkin. There are 93 atoms in vitamin B_{12} (excluding hydrogen, which is so light that its position cannot be found by ordinary X-ray methods); but even a small protein molecule like myoglobin contains more than ten times as many atoms as does the molecule of vitamin B_{12}, and it is simply beyond the scope of the method in its present state of development to contemplate determining the complete structure of a molecule as complicated as this, in the sense of discovering the exact relative positions of all its atoms. All that can at present be hoped for is to find out something about the general layout of the molecule—its tertiary structure, in fact.

One may regard each spot in the diffraction pattern of a crystal as corresponding to a train of waves running through the crystal. If all the waves are added together the result is a representation of the distribution of matter throughout the repeating unit (or unit cell) of the crystal, just as the wave-form of a musical note can be reconstituted by adding together the harmonics into which it may be analysed. If the waves are to be correctly combined, it is necessary to know four things about each: its direction, its wave-length, its amplitude, and its phase. The first three can be determined immediately by measuring the X-ray diffraction pattern; but the phase—the amount by which each wave is out of step with its neighbours—cannot be discovered directly by any physical method. This is the so-called phase problem of X-ray crystallography—if the phases could be found by direct measurement, X-ray structure determination would simply be hard work: as it is, cunning is needed as well as industry.

Simple structures have often been worked out by the trial-and-error method, which in essence consists in making intelligent guesses on the basis of previous knowledge about the molecule being studied. In proteins, however, the structure is too complicated for anyone to be able to make such guesses. Since the first X-ray pictures of protein crystals were taken by Bernal and Crowfoot in 1934, a large number of theories of protein structure has been based on them, but these were all speculative and, as it has turned out, much over-simplified. Speculation gave place to hard fact only as a result of the discovery, by Perutz in 1953, that it was possible to apply to protein crystals the so-called method of isomorphous replacement, which had often been applied to simpler structures, but which no one had, until then, shown could be used to study anything as complicated as a protein. The essence of this method is to add to each protein molecule in the crystal a single very heavy atom, such as mercury or gold; this has the effect of slightly changing the intensities of most of the spots in the diffraction pattern. It turns out that, by comparing the diffraction patterns of two crystals which differ only in the inclusion of the heavy atom in one of them, it is possible to solve the phase problem by an unambiguous procedure which does not involve guesswork.

Perutz applied this method to hæmoglobin, and by its use he was able to obtain a two-dimensional projection of the structure, as it were a silhouette of the molecule. This projection was derived by straightforward deductive methods, and it is certainly correct; but, unfortunately, the two-dimensional silhouette is so confused owing to overlapping that one can learn from it virtually nothing of the spatial arrangement of the atoms composing the molecule. In hæmoglobin one is actually 'looking through' the thickness of some forty atoms, so it is not surprising that the projection is uninterpretable. We subsequently applied the same method to myoglobin, the molecule of which is only one-quarter the size of hæmoglobin, and derived a similar two-dimensional projection which proved to be equally obscure.

It was clear that the only way to make progress was to extend the method to three dimensions. Such an extension is not easy, for several reasons. First, in order to get an unambiguous result in three dimensions it is necessary to compare the diffraction patterns of several crystals, each containing a heavy atom in a different place; secondly, the computations involved in determining the phase of each reflexion are more tedious than in two dimensions; and thirdly, for any desired resolving power it is necessary to examine far more reflexions.

In our recent studies on myoglobin we were able to attach four different heavy atoms at different places on the molecule, and to compare the diffraction patterns of each of the resulting substituted crystals with that of the protein alone. As to resolving power, the number of reflexions which must be included in the calculations in three dimensions is proportional to the cube of the resolution desired. Individual atoms are 1–2 Ångström units apart, and to see them separately would demand a resolution of at least 1·5 A., involving the measurement of more than 20,000 reflexions per crystal. Our plan was to try out the method, and to gain a first look at the structure, at low resolution. We chose the figure of 6 A., because at this resolution one might expect to see the polypeptide chains if they were in some compact configuration such as the α-helix: to attain this resolution it is only necessary to study 400 reflexions from each crystal.

The work of measuring these reflexions for crystals of myoglobin and of each of five different substituted myoglobins was carried out in the Medical Research Council Unit for Molecular Biology at the Cavendish Laboratory, Cambridge, and at the Davy Faraday Laboratory of the Royal Institution, in collaboration with Drs. Bluhm, Bodo, Dintzis, Phillips, Wyckoff and Miss Mary Pinkerton. After completing the calculations needed to determine the phases of all the four hundred reflexions, we computed an electron density map on the electronic computer EDSAC at Cambridge; this calculation was checked by Dr. Rollett, who repeated the computation on DEUCE at the National Physical Laboratory. The result was plotted in the form of sixteen sections through the unit cell, piled up (like the serial sections of organs used by anatomists) to give a three-dimensional representation of the density of matter throughout the unit cell, the density at each point being represented by contours (Fig. 2).

It was gratifying to discover that in the resulting three-dimensional synthesis there were indeed numerous rod-like features of just the dimensions and density to be expected of polypeptide chains arranged in a helical configuration. It is not easy to see these rods except by looking at the synthesis itself, but some of them are visible in the right-hand half of Fig. 2. There is little doubt that these rods are actually blurred representations of the polypeptide chains, and by adding up all the visible lengths of rod we can account for some two-thirds of the whole molecule.

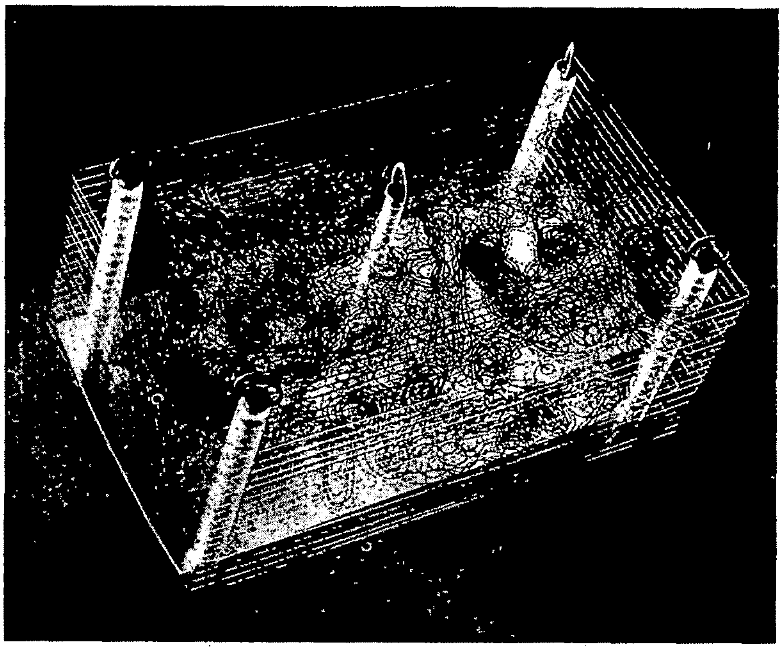

Fig. 2. Photograph of the three-dimensional electron density map of the unit cell of myoglobin. Two polypeptide chains can be seen on the right: the dense peak between them is the hæm group

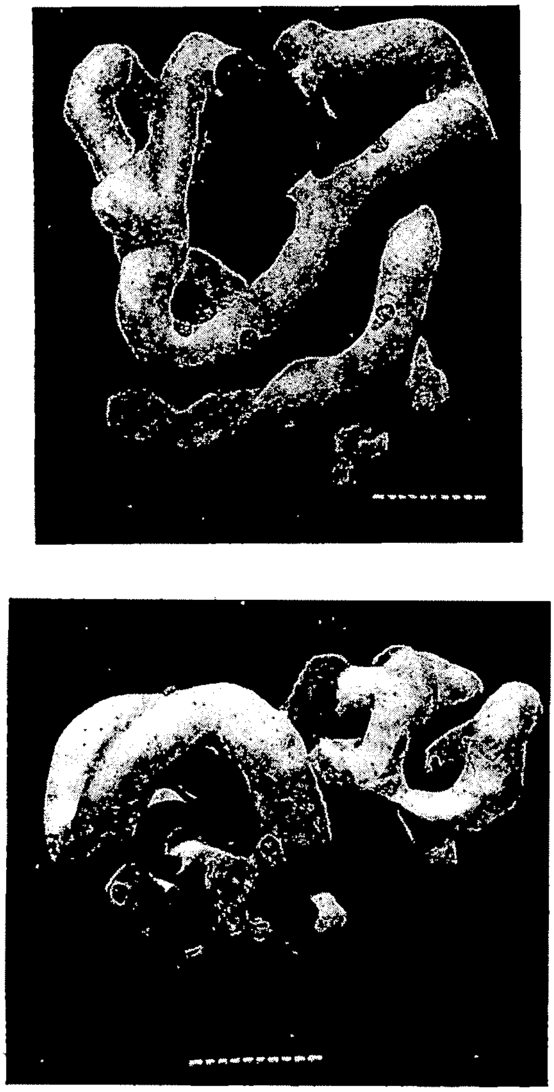

Fig. 3. Photographs of a model of the myoglobin molecule. The marks on the scale are 1 A. apart. The grey disk is the hæm group; the pair of small spheres attached to it is an oxygen molecule on the same scale. The larger spheres are heavy atoms used to solve the crystal structure

Another prominent feature of the synthesis is a flattened disk-like region the density of which exceeds the mean by some 50 per cent more than does that of any other part of the map. We think that this region is the hæm group itself, the high density being contributed by its central iron atom, the heaviest atom in the myoglobin molecule. The identification is confirmed by the orientation of the disk relative to the axes of the unit cell, which corresponds with the hæm group orientation deduced from a study of the optical and magnetic properties of the crystal; and also by the fact that one of the heavy atoms we were able to attach to myoglobin, the iodine atom in *p*-iodophenylhydroxylamine, which is known to be a specific reagent for the hæm group itself, has been located in the immediate neighbourhood of the disk.

The unit cell of myoglobin actually contains two molecules of protein, related by a symmetry axis (a screw dyad), and the electron density map likewise contains two molecules, each with its own hæm group and polypeptide chains. Furthermore, the two molecules in a single unit cell are closely surrounded by the molecules of neighbouring unit cells. To get an idea of the structure of a single myoglobin molecule one must, as it were, dissect out a single molecule from its neighbours. To do this, we make use of the fact that a protein crystal generally contains up to 50 per cent of liquid, which fills up the interstices between the protein molecules. In the electron density map we can recognize these interstices, because the liquid is featureless and has uniform electron density. Once the interstices have been located, the boundaries of a single molecule can be outlined in a straightforward manner.

Fig. 3 shows two photographs of a model of the single molecule thus separated from its neighbours. The sinuous white rods are the backbone of the polypeptide chain: it must be remembered that in reality these backbones are clothed with a layer of side-chains (invisible at this resolution) so thick that each polypeptide chain is in contact with its neighbours. Also marked is the hæm group, a flat grey disk; and on it are two spheres which represent an oxygen molecule and which have been included to convey some idea of the scale of the model, although, of course, they cannot actually be seen in the electron density map. The model also shows some of the heavy atoms which were attached to the molecule in order to solve the phase problem.

Chemical evidence indicates that myoglobin consists of just one single polypeptide chain, made up of 153 amino-acid residues. In the model this chain pursues a complicated winding path throughout the molecule, which has overall dimensions about 43 × 35 × 25 A. It may be asked whether it is possible to trace the course of the chain unambiguously through the molecule: in most places this can be done, but in some, for example, where it turns through a particularly sharp corner, the chain fades out at the resolution used in this map, and one cannot be sure of its course. It is clear that whenever the chain turns a corner it must lose its helical configuration for, as has already been pointed out, an arrangement such as the α-helix is essentially straight and cannot bend without ceasing in effect to be a helix at all: at the resolution of 6 A. an extended polypeptide chain would scarcely be visible. Measurement of the total length of chain in the model suggests that it is a helix for some 70 per cent of its length, a proportion which agrees well with estimates based on other techniques.

All in all, the model poses more questions than it answers. It gives us a first glimpse of the configuration of a protein molecule, but it is a tantalizing glimpse because the picture is so blurred that one cannot recognize side-chains, nor be certain how the backbone is folded—even whether it is a helix at all—nor know how the hæm group is attached to the rest of the molecule. Many of these questions could be cleared up if an electron density map could be drawn at higher resolution, even if that resolution stopped short of separating individual atoms. There seems no reason in principle why the resolution should not be improved, although an extension to atomic resolution is at the moment beyond our reach. At present, data are being collected for the 10,000 reflexions out to 2 A., and we hope that the electron density map prepared from these will in due course show us some of the finer details of the structure.

NEWS and VIEWS

Ministry of Supply : Scientific Research (Electronics and Guided Weapons) : Dr. E. V. D. Glazier

Dr. E. V. D. Glazier, who holds the post of director of Scientific Research (Electronics and Guided Weapons) in the Ministry of Supply, has been promoted to the rank of deputy chief scientific officer. Dr. Glazier, who was born in 1912, had his early training in general electrical and mechanical engineering in industry, joining the Engineer in Chief's Office of the General Post Office in 1933, when for the ensuing nine years he was engaged on the development of telephone systems. He graduated in the University of London and was awarded the degree of Ph.D. In 1942, he transferred under war-time arrangements to the Signals Research and Development Establishment, joining the Line Communication Group where he was responsible for the development of a wide range of signals equipment for the Army. He became head of the Line Communication Group in 1946, having in the interim spent two years in the Ministry of Supply headquarters. In 1950, he was transferred to lead the Research Division at Signals Research and Development Establishment and under his leadership the research group there made significant advances in a number of radio and electronic systems for Army use. In 1957, he returned to headquarters so that his practical training and research knowledge could be employed in advising on and co-ordinating the present and future research in electronics in the Ministry of Supply as a whole. Dr. Glazier is the secretary of the Radar and Signals Board of the Scientific Advisory Council. He is one of a band of people who, having moved progressively from application to research, are of very great value in the senior ranks of the Ministry of Supply.

Ministry of Supply : Electronics Research and Development : Dr. J. S. McPetrie

Dr. J. S. McPetrie has been appointed director general of Electronics Research and Development in succession to Dr. D. H. Black (see *Nature*, 182, 225 ; 1958). Dr. McPetrie has had a long and distinguished careeer in radio research. He joined the Radio Research Station of the National Physical Laboratory from the University of Aberdeen, and was engaged on early research on aerials and propagation at very high frequencies. He also explored methods of generating the progressively shorter wave-lengths required for this work. He was the author of several early papers on the properties of metric waves. During the Second World War he joined the Ministry of Supply and was lent to the British Commonwealth Scientific Office in Washington. At the end of the War he returned to take charge of the newly formed Research Division at the Signals Research and Development Establishment, Christchurch, where he was responsible for a wide range of research problems in radio and electronics for the Army. In 1950, he was promoted to be in charge of the Radio Department at the Royal Aircraft Establishment, where he was responsible for research and development in aircraft radio and navigational systems.

Dr. McPetrie has been a leading member of the Institution of Electrical Engineers for more than 25 years, and he was honoured recently by election as chairman of the Radio Section for the session 1957–58. His year of office was notable for the number of highly successful meetings and international conferences that were organized. In his new appointment Dr. McPetrie will be responsible for research and development in communications and radar for the Naval Air Branch, Army and the Royal Air Force, and for many of the other fields in which electronic devices are contributing to defence and civil aviation.

British Scientific Attaché in Moscow

The Department of Scientific and Industrial Research has announced that a senior principal scientific officer is to be appointed scientific attaché to the British Embassy in Moscow (see *Nature*, 182, 292 ; 1958). There are at present only four British scientific attachés, namely those attached to H.M. Embassies at Washington, Paris and Bonn, with one scientific attaché attached to the Embassies at Stockholm, Oslo and Copenhagen, and working between them. Their duties include reporting on scientific developments in the countries in which they serve and advising the ambassador on scientific questions.

Science Laboratories in Schools

A table circulated by the Parliamentary Secretary to the Ministry of Education, in reply to a question regarding part-time day release in industry, shows that the percentage of boys under eighteen released to attend part-time day classes in 1956–57 has risen to 33·8 (from 27 per cent) and of girls to 8·5 (from 7 per cent). On July 24 Sir Edward Boyle gave the estimated capital cost of new science laboratories started in 1957–58 at schools maintained by local education authorities as £1,100,000 and of those due to start in 1958–59 as £2 million ; of these figures £350,000 and £550,000, respectively, were at grammar schools ; £600,000 and £1,200,000 at modern schools ; and £150,000 and £250,000 at technical secondary schools. Questioned further on July 31, Sir Edward said that extensions to science accommodation at more than 100 grammar schools had been approved for the 1958–59 and 1959–60 building programmes. Although a recent survey reported in the *School Science Review* indicated that less than 10 per cent of maintained grammar schools had reported adequate science laboratories, 44 per cent of the schools had science accommodation conforming with the suggestion made in the Ministry's building bulletin.

Préhistoire Spéléologie Ariègeoises

The activities of the Société Préhistorique de l'Ariège are not as well known as they should be. The first bulletin for 1946 appeared in 1948 and the present one under review is No. 12 (pp. 152+7 planches. Tarascon-sur-Ariège : M. Romain Robert, Place Jean-Jaurès, 1957). One of the better accounts of the great painted cave of Niaux from the pen of Abbé Breuil will be found in No. 5. Each number has been full of interesting articles. The present number is no exception, and it contains many good papers : the rhinoceros and the cave bear as depicted in upper palæolithic art ; aurignacian art in central Europe ; notes on the Neolithic finds in the Department of the Aude ; several shorter accounts of various activities of the Society. Publications by local societies tend to be overlooked and are not always easy to obtain. But prehistorians would be wise to keep in mind the activities of this flourishing society in the Ariège and their energetic president, Monsieur Robert.

Journal of the Institute of Wood Science

In 1957 the Institute of Wood Science was inaugurated for the advancement of timber research and technology, and the first number of the Society's journal has now been published (*Journal of the Institute of Wood Science*, No. 1, March 1958. Pp. i+64. 15*s*.). Its scope is to include original papers, both in research and in technology, and reports of lectures and discussions at the Society's meetings. Research on timber is a very wide subject and involves many scientific disciplines, biological, physical, chemical and engineering, and the new journal should have a varied and interesting range of papers to publish. This is reflected in the first number, the contents of which includes such diverse subjects as variations in structure occurring during growth, the physiology of cambial activity, ultrasonic-pulse technique in investigations of strength, and the acidity of wood. All, as would be expected, have practical application in view, so that the journal should have appeal both for scientific and technological workers alike.

A New Estonian Natural History Journal

The Academy of Sciences of the Estonian Soviet Socialist Republic has produced a new journal of science, *Eesti Loodus* (Estonian Nature). Published bi-monthly, the articles are written in Estonian; but each issue contains abstracts in the English language which have been prepared by a translator with a remarkable flair for the right word and phrase. The articles cover a wide range of subjects including such topics as the artificial earth satellite; cliffs of the Jaagarahu Strata; Virginia witch-hazel in the Estonian S.S.R.; insects on snow; the practical application of the infra-red quenching of luminescence; the dependence of the external form of tetracorals on environmental conditions; the distribution of steppe plants and phytogeographical boundaries in Estonia; the 'Snowman'; ball lightning; the Elva Sandr, its formation and early hydrography; plant parasitic nematodes in Estonia and the protection of inanimate nature in the Estonian S.S.R. Each number also contains a section giving details of outstanding scientific discoveries as well as popular sections for young people and general readers. The editorial office is 5 Hariduse Street, Tartu, Estonian S.S.R.

The Geological Museum

The Geological Museum at South Kensington has just issued an attractive short guide to the exhibits (pp. ii+32. London: H.M. Stationery Office, 1958. 1*s*. 6*d*.). The publication is intended primarily for the visitor who wishes to make a short tour of the Museum and obtain a general idea of the scope of the display collections. At the outset is given a short history of the Museum and a sketch plan of the general arrangement. The three floors are then described in more detail again, with plans of particular sections. The general arrangement of the guide thus conforms with previous editions. The format is good and pleasing, though it is unfortunate that the method of reproduction of the photographic illustrations scarcely does justice to the originals.

The Wild-Fowl Trust

Besides a wealth of characteristic sketches by the Director, the ninth annual report of the Wild-Fowl Trust contains a remarkable collection of photographs of wild-fowl taken by some of the world's best natural history photographers (edited by Peter Scott and Hugh Boyd. London: Country Life Limited, 1958. 10*s*. net). Then there is a series of articles by members of the staff and friends of the Trust which not only records developments and researches at Slimbridge but also describes wildfowl collections and investigations in many other parts of the world. Probably the biggest event in the life of the Trust during 1956–57 was the opening of the Peakirk Waterfowl Gardens by H.R.H. the Duke of Gloucester on April 12, 1957. One of the main objects of this scheme is to provide sufficient funds to enable the Trust to take on the lease and maintenance of Borough Fen Decoy, which has been operated by members of the Williams family since its construction in about 1640. It is also of great value to have a place which can be used as a reservoir for birds, and an alternative collection, as the danger of epidemics among the birds at Slimbridge cannot be entirely dismissed.

During the period popular interest in the collection at Slimbridge continued to grow in a gratifying way. The total number of visitors in the calendar year 1956 was about 120,000. In 1957 this figure was reached before the end of August. Membership stood at 5,094 in January 1957—another record figure. The collections at Slimbridge and Peakirk now contain about 1,747 birds of 148 forms (116 species). In 1957, 770 young birds, of 72 forms, were reared in the collection. Extensive studies have begun in two fields new to the Trust's research programme: a systematic investigation into the food of wild fowl and the use of aircraft in surveys of the distribution and number of wildfowl.

Demonstration Meeting on Biological Acoustics

During the fifteenth International Congress of Zoology, held in London during July 16–23, the Committee for Biological Acoustics organized a demonstration meeting to illustrate the wide range of research in this comparatively new and expanding field. The meeting, held on July 21 in the Imperial College of Science and Technology, London, was open to all members of the Congress and attracted more than one hundred visitors. Work on the reception of human speech was shown by Dr. E. C. Cherry and colleagues of the Department of Electrical Engineering, Imperial College, and demonstrated how recognition of electronically 'clipped' speech is accomplished. Binaural location of sounds was also shown. The progress made in the United States in underwater recording was emphasized by a demonstration of the acoustic emission of whales by Dr. W. E. Schevill, of the Oceanographic Institution, Woods Hole, Massachusetts. The technical problems inherent in such studies were made apparent by recordings of American marine noises made by Dr. Martin Johnson, of the Scripps Institution of Oceanography, University of California; a high-level background noise interfering with recording of fish noises was eventually traced by him to its origin in large populations of 'snapping shrimps'. The single, irregular cracking noise produced by each individual shrimp drifting in the sea, when multiplied by the number of shrimps within range of the microphone, produces a frizzing background noise of high level. British interest in underwater acoustics was underlined by Mr. N. B. Marshall, of the Department of Zoology, British Museum (Natural History), who said that it was hoped that a start would soon be made on recording in the English Channel.

Bird sounds were introduced by Dr. R. G. Busnel, director of the Laboratoire de Physiologie Acoustique, France, who, in collaboration with Prof. H. Frings, of Pennsylvania State University, has recorded the songs of French and American crows to see if their sound signals were similar, or if they had evolved separate 'dialects' of their own. Dr. J. H. Elgood, Biology Department, Ibadan, Nigeria, played some recordings of the songs of Nigerian birds in the wild. Insect acoustics was represented by several workers. Dr. J. W. S. Pringle, Zoological Laboratory, Cambridge, played recordings made by him in Ceylon of the songs of several species of cicadas, and Mr. E. F. Woods, of the B.B.C., demonstrated his work on the sounds of colonies of honey bees, while developing an electronic device, the 'Apidictor', which can assist apiarists in detecting the onset of swarming in hives. Mme. G. Richard, Laboratoire de Zoologie, Rennes, demonstrated recordings of the underwater noises made by corixids, while Dr. W. Loher, Department of Zoology, Imperial College, and Dr. P. T. Haskell, Anti-Locust Research Centre, London, showed some results of their investigations on the stridulation of grasshoppers. Much of the discussion, both public and private, which developed out of the demonstrations was concerned with techniques and instrumentation, and it was therefore helpful that a number of firms, including Ferrograph, E.M.I. and Grundig, had lent apparatus for demonstration.

Time Rates of Wages and Hours of Labour

THE twelfth edition of "Time Rates of Wages and Hours of Labour", compiled by the Ministry of Labour and National Service (London: H.M. Stationery Office, 1958. 15*s*. net), contains the usual tables which show, for the majority of industries and occupations, the minimum or standard time-rates of wages, the dates from which these rates become operative, and the normal hours of labour. The rates of wages and hours of labour are those determined by voluntary agreements between organizations of employers and workpeople, or made by Joint Industrial Councils or other similar bodies, or by Statutory Orders under the Wages Councils Acts, the Agricultural Wages Acts and the Catering Wages Act. Particulars are also given, where available, of the basic rates for pieceworkers, the additional rates payable to shift and night workers, and, where they are known to exist, of the arrangements for a guaranteed weekly wage or period of employment. Three appendixes give details of rates of wages for young workers in a selection of industries, and of overtime rates of pay, and arrangements for paid holidays in the industries included in the main part of the volume.

Scientific Film Association

THE sixth annual report of the Council of the Scientific Film Association, for the year ended March 31, 1958 (pp. 12. London: Scientific Film Association, 1958), records an increase in membership from 324 to 404 during the year, and the six issues of the *Scientific Film Review* provided technical and distribution details on 335 films; similar information and a synopsis of content for a further 324 films; and full reviews or appraisals of another 451 films. Three catalogues were published during the year with detailed reviews and appraisals of 44 films on cerebral palsy, 100 films on education and 131 films on psychology and psychiatry. The film appraisal work is under continual development and a report on "The Evaluation of Scientific, Industrial and Medical Films" previously published in the *Scientific Film Review* will shortly be re-issued as a pamphlet. The Association has dealt with a wide range of inquiries about films and film making, and besides arranging a varied programme of meetings, held a residential course at Kingsgate College in March on the use of films in supervisory training. As the national representative, it plays an active part in the work of the International Scientific Film Association.

Semi-conductors

A VALUABLE guide to the use of semi-conductor devices, compiled by a committee consisting of representatives of fifteen manufacturers of semi-conductor devices in the United Kingdom, has recently been published on behalf of the manufacturers by the British Radio Valve Manufacturers' Association (The Use of Semi-conductor Devices. Pp. iv+36. London: British Radio Valve Manufacturers' Association, 1958). It is intended to assist equipment designers to secure optimum performance and life from the devices, which consist basically of monocrystalline material. In the case of diodes and transistors the substances are either germanium or silicon, and in the case of photosensitive devices they include also compound semi-conductors such as lead selenide or indium antimonide. The booklet is divided into four sections dealing with, respectively, general considerations, for example, frequency limitations, ratings, temperature and high-energy effects, of semi-conductor devices; semi-conductor diodes; junction transistors; and photo-sensitive devices. The information given is very carefully and clearly set out. A detailed index allows easy and quick reference to any particular item discussed in the guide.

Low-Temperature Thermometer

EMPHASIS on low-temperature research, particularly low-temperature calorimetry, has highlighted the need for a thermometer which indicates low temperatures accurately and reliably and does not need continual calibration. Germanium can be doped with arsenic to produce a high and fairly constant temperature coefficient at temperatures near to the boiling point of helium, and a germanium resistance thermometer of high sensitivity and exceptional stability in the temperature range near to the absolute zero has been developed by J. E. Kunzler, T. H. Geballe and G. W. Hull of Bell Telephone Laboratories Ltd. The thermometer consists of a single crystal of arsenic-doped germanium, $0\cdot025 \times 0\cdot020 \times 0\cdot210$ inches, with attached current and potential leads and supported in a strain-free manner in a platinum-glass enclosure filled with a small amount of helium. Temperature is determined by measuring the potential drop due to resistance when a current of approximately 10^{-7} amp. is passed through the germanium crystal. A typical thermometer had a resistance of one ohm at room temperature, 14 ohms at 10° K. and 216 ohms at 2° K., but both the temperature coefficient and the actual resistance vary widely with minute changes in the amount of doping, so that thermometers of differing characteristics can be made. Once calibrated the thermometer is reproducible to better than a few ten-thousandths of a degree at the boiling point of helium (4·2° K.) even after repeated cycling from room temperature to 1° K.

Megaspore Tetrads in a Coenopterid Fern

W. G. Chaloner has observed and described a new type of fossil spore tetrad, *Didymosporites scotti gen. et spec. nov.*, from Carboniferous strata in Ireland, Scotland and England, which may be the megaspores of the cenopterid fern *Stauropteris burntislandica* (*Annals of Botany*, N.S., 22, 197; 1958). The spores always occur as tetrads consisting of two large and two minute spores with cutinized walls, the former presumably fertile, the latter abortive. The evidence from studies of the distribution of these spores indicates that this species was much more widely distributed in time and space than has been previously known. The conformation of the coherent tetrads raises the question as to whether they were 'shed' while still within the megasporangium, as in *Lepidocarpon* and pteridosperm seeds.

Combustion Institute Awards

Dr. Bernard Lewis, president of the Combustion Institute, Pittsburgh, Pennsylvania, is the first recipient of the Institute's Bernard Lewis Medal awarded "for brilliant research in the field of combustion, particularly on minimum ignition energy". The Alfred C. Egerton Medal of the Institute was awarded to Sir Alfred Egerton, professor emeritus of the Imperial College of Science and Technology, London, and chairman of the British Section of the Combustion Institute, "for his distinguished, continuing, and encouraging contributions to the field of combustion". The Combustion Institute Silver Medal was awarded to Prof. Seiichiro Kumagai and Hiroshi Isoda, of the University of Tokyo, in recognition of "an outstanding paper presented at the Sixth Symposium on Combustion" at Yale University in 1956. Similar awards will be made at each biennial symposium. The Eighth International Symposium on Combustion will be held in 1960 at California Institute of Technology, Pasadena.

X-Ray Analysis and Electron Microscopy of Metals

The X-ray Analysis and Electron Microscopy Groups of the Institute of Physics will hold a joint conference on "Precipitation in Alloys" on Friday, November 28, at the Institution of Civil Engineers, Great George Street, London, S.W.1. On the previous day the Electron Microscopy Group will hold a symposium on "Electron Staining" at the Royal Society of Arts, 6–8 John Adam Street, W.C.2, while on the day following the joint conference, the X-ray Analysis Group will discuss the examination of metals by X-ray diffraction at a meeting at the Institution of Civil Engineers. An exhibition of apparatus, etc., is being arranged at the Institution of Civil Engineers. Non-members of the Institute of Physics may attend these meetings; they should complete an application form to be obtained from the Honorary Secretary of the X-ray Analysis Group, Dr. R. L. Gordon, Safety in Mines Research Establishment, Portobello Street, Sheffield 1, from whom further information may be obtained.

Announcements

Mr. E. Lord of the British Cotton Industry Research Association has been awarded the Warner Medal of the Textile Institute.

Dr. Roger Revelle, director of the Scripps Institution of Oceanography, University of California, has now been appointed to the additional post of director of the University's new Institute of Technology and Engineering at La Jolla.

Prof. R. H. S. Thompson, professor of chemical pathology in the University of London at Guy's Hospital Medical School, Prof. E. J. Wayne, regius professor of the practice of medicine in the University of Glasgow, and Prof. B. W. Windeyer, professor of radiology in the University of London and director of the Meyerstein Institute of Radiotherapy at the Middlesex Hospital, have been appointed members of the Medical Research Council.

The following research studentships for postgraduate training in ecology, tenable for periods up to three years at the universities shown, have been awarded by the Nature Conservancy: *Botany:* J. M. Bradbeer (Southampton), D. Briggs (Durham), T. T. Elkington (Durham), P. J. Myerscough (Oxford), J. G. B. Newbould (Oxford), B. M. Stephens (University College of North Wales, Bangor); *Zoology:* N. G. B. Jones (Oxford), P. O'Donald (Cambridge), Miss R. M. Oldroyd (London), Miss E. A. Steel (Reading); *Geography:* J. C. Rodda (University College of Wales, Aberystwyth).

Awards for study in statistics by persons whose primary field is not statistics but one of the physical, biological or social sciences to which statistics can be applied are offered by the Department of Statistics of the University of Chicago. The awards range from 3,600 to 5,000 dollars on the basis of an eleven-month residence. The closing date for application for the academic year 1959–60 is February 16, 1959. Further information can be obtained from the Department of Statistics, Eckhart Hall, University of Chicago, Chicago 37, Illinois.

The twenty-fifth Annual Conference of the National Society for Clean Air will be held in Llandudno during October 1–3. Further information can be obtained from the Society at Palace Chambers, Bridge Street, London, S.W.1.

A meeting of the North of England Section of the Society for Analytical Chemistry will be held on October 4 at the City Laboratories, Mount Pleasant, Liverpool, 3, to discuss "Laboratory Balances".

The Antiquarian Horological Society is holding a meeting in Birmingham on October 4. Further information can be obtained from Mr. A. K. Soper, 29 Furham Field, Hatch End, Middlesex.

The eleventh Annual Conference on "Electrical Techniques in Medicine and Biology" will be held in Minneapolis, Minnesota, during November 19–21. It is sponsored by the Institute of Radio Engineers, the American Institute of Electrical Engineers, and the Instrument Society of America through their Joint Executive Committee on Medicine and Biology. Abstracts of two hundred and fifty words for short contributed papers offered for inclusion in the programme may be sent by October 1 to Mr. Robert Erskine, Minneapolis-Honeywell, 2753 Fourth Avenue South, Minneapolis, Minnesota, from whom further information can be obtained.

Erratum: In the communication entitled "Hæmoglobin *P* (the 'Galveston' Type)" by Dr. Rose G. Schneider and Dr. Mary Ellen Haggard, published in *Nature* of August 2, p. 322, the symbol μ (ionic strength) should be substituted for the symbol M (molar) throughout the text and in the legends of Figs. 1 and 2.

HIGH POLYMERS

AN International Conference on High Polymers was held at the University of Nottingham during July 21–24. This Conference, which was organized by a British committee under the chairmanship of Sir Harry Melville, was attended by nearly six hundred scientists, including an official delegation of twelve Russians and altogether 150 foreign specialists—from twelve nations—in the physics and chemistry of high polymers.

The Conference provided a timely opportunity for a full exchange of views between those working in the high-polymer field at universities and in industrial and government research laboratories. The main themes selected for discussion were : (*a*) reaction mechanisms and kinetics with special reference to heterogeneous polymerization, including trapped radicals. Production of graft and block co-polymers; (*b*) physical, thermodynamic and mechanical properties of high polymers. The papers, which were preprinted and circulated before the meeting, were limited to forty-four.

It is now becoming accepted practice at international polymer meetings for Prof. H. Mark of the Polytechnic Institute of Brooklyn, New York, to deliver the opening address, and on this occasion he summarized in a masterly manner recent developments in the preparation and synthesis of stereospecific polymers, and the structural importance of helical configurations in understanding the properties of these polymers.

The discovery in 1953 by Karl Ziegler that catalysts formed by interaction of a metal alkyl of groups I, II and III elements with certain transition metal compounds polymerize ethylene rapidly to a high molecular weight polyethylene at room temperature and atmospheric pressure opened up a wide and important field of the study of heterogeneous polymerization, and several papers were devoted to a study of the mechanism of the action of Ziegler catalysts. Many catalytic systems have been found to be equally effective in polymerizing ethylene and other olefins at low pressures, and one of the Russian papers dealt with the use of chromium and molybdenum oxides for this purpose. Catalysts of this type are used commercially in the United States for the synthesis of polyethylene of high molecular weight. There is much evidence that soluble complexes formed by interaction of certain titanium compounds and metal alkyls polymerize ethylene in solution at normal temperatures and pressure homogeneously, although at a rate much lower than that of typical heterogeneous catalysts. Catalysts of this kind are probably more amenable to mechanistic study,, and detailed experimental kinetic results were presented on the polymerization of ethylene by homogeneous catalysts made from the interaction of aluminium triethyl and *sec*-butyl titanate, and zinc di-*n*-butyl and titanium tetrachloride in hydrocarbon solvents. Kargin and his colleagues (Moscow) reported that the mechanical properties of ethylene polymers made from catalysts formed by the interaction of organo-lithium compounds with titanium tetrachloride showed marked differences depending on the structure of the organic metallic component of the catalyst.

The most important development in the study of heterogeneous polymerization of the above type was the synthesis in 1954 by Natta and his co-workers at the Milan Polytechnic of α-olefin polymers with regular, linear, head-to-tail structures and the separation of the synthetic product into isotactic and atactic polymers. The stereospecific configuration of the former was established by X-ray methods, and a study of the nature of the catalysts enables the stereospecificity of the heterogeneous catalysts to be controlled. In this way many crystalline poly-α-olefins and di-olefins of definite stereochemical structure were synthesized for the first time. In the opening paper of the general discussion, Natta described his very extensive investigations on the kinetics of α-olefin polymerization and co-polymerization of ethylene with α-olefins. The decomposition of aliphatic diazo compounds by boron trifluoride and other boron compounds has been known for a long time to yield polymethylene of high molecular weight. From a kinetic study of this reaction Bawn and Ledwith proposed a polymerization mechanism involving boron alkyl as the true catalyst. They suggest that the polymerization is analogous to Ziegler-type polymerization of α-olefins and occurs by co-ordination with the boron, and that this results in a successive series of insertions of monomeric units into a boron–alkyl bond. An interesting example of anionic polymerization was discussed by Overberger and co-workers (Brooklyn), who postulated that the initiation process of the polymerization of methacrylonitrile in liquid ammonia is a one-electron transfer from lithium to the monomer to give an anion radical.

In 1955 it was reported in the patent literature that propylene oxide could be polymerized by ferric chloride to give products of high molecular weight which were partially crystalline. C. C. Price (1956) showed that if an optically active monomer is used the activity is retained in the crystalline polymer, and the mechanism of polymerization suggested by Price is analogous to that proposed by Natta for the heterogeneous polymerization of α-olefins. In a series of papers, C. C. Price and co-workers (University of Pennsylvania) and G. Gee and collaborators extend these investigations to other olefin oxides and show that a wide variety of catalyst systems—Lewis acid metal alkoxides, mixture of alkoxides and halides or metal halides—serve for the polymerization of propylene and other olefin oxides.

Many of the kinetic features of the polymerization of vinyl monomers in conditions in which the polymer formed is precipitated may be explained in terms of occlusion of precipitated free radicals of polymer chains. Bamford, Jenkins, Symons and Townsend reported results of the concentration of trapped polyacrylonitrile radicals as determined by electron resonance spectroscopy and the variation of this concentration with experimental conditions such as degree of swelling of the polymer, rate of photo-initiation and temperature. The fraction of radicals which become trapped was shown to be about 12 per cent in the bulk polymerization of acrylonitrile. Electron spin resonance measurements were also used by Atherton, Melville and Whiffen to follow radical concentrations in the co-polymerization of methyl methacrylate and glycol dimethacrylate.

F. S. Dainton and co-workers summarized their extensive and detailed studies on the polymerization of acrylonitrile in aqueous solution when initiated by : (*a*) Fenton's reagent, and (*b*) photochemically, using various photosensitizers. By means of the rotating sector technique they have determined both k_p and k_t and also elucidated: (1) the mechanism of the termination reaction by salts of metals of variable valency; (2) the effect of coagulation on the rate of polymerization. Other interesting observations on heterophase polymerization which were reported and discussed were: (*a*) the increase in rate of the high-energy initiated polymerization of isobutene by the presence of metal oxides of high surface area; (*b*) the effect of the physical nature of the separating phase on the rate of the heterogeneous polymerization of acrylonitrile and methyl methacrylate by Palit and Guha (Calcutta); (*c*) the co-polymerization of water-soluble sodium methacrylate with methyl methacrylate maintained in a fine particle size with the aid of water-soluble colloids.

Block and Graft Co-polymers

The general methods of synthesis of graft co-polymers have been fairly well worked out during the past ten years, and the group of papers presented to the discussion largely elaborated and consolidated these procedures, particularly with reference to the utilization of ionizing radiation, interaction of functional groups of macromolecules with monomeric and polymeric substances, and the initiation of monomers by macro-radicals. Various syntheses of graft and block co-polymers have been described in which polymers containing peroxides, hydroperoxides and perester groups may be used as initiators for the second-step polymerization, and Prof. G. Smets and co-workers (Louvain) presented kinetic results obtained with polymethylacrylate co-polymers containing *tert*-butyl perester groups and styrene monomer. A new method of synthesis of block co-polymers proposed involved the synthesis of polymers containing peroxide end-groups and the metal salt catalysed decomposition of the peroxide group in a second monomer. Prof. A. Berlin (Moscow) described the synthesis of graft co-polymers of branched structure by the polymerization of a number of monomers in latexes of polyvinyl chloride and synthetic rubbers. The preparation and kinetics of formation of block co-polymers from a primary polymer with amine end-groups which may be used as a macromolecular transfer agent and also the formation of graft co-polymers using a primary polymer with terminal double bond which co-polymerizes with a second monomer were described by Bamford *et al.* Wichterle and Gregor (Prague) reported the preparation of polymers of N-methacryloyl caprolactam. Polymer amides prepared in this way were shown to catalyse the polymerization of caprolactam, and the resulting grafted co-polymers had a three-dimensional structure. Caprolactam reacts with styrene–methyl methacrylate co-polymers to form soluble graft co-polymers, the properties of which have been studied by Chapman and Valentine. The mechanism and properties of grafts formed by polymerizing vinyl acetate monomer in the presence of polyvinyl alcohol and an alkali and a water-soluble persulphate catalyst were discussed by Hartley, and those of polymethyl methacrylate graft to natural rubber by Kobryner and Banderet (Strasbourg).

The recent interest in the use of radiation to produce new polymer hybrids has spurred a great deal of research, and four papers presented on this subject dealt mainly with grafting of vinyl monomers to polyethylene film. In general, four methods were described for producing such co-polymers: (1) Simultaneous grafting—the film being irradiated while immersed in, or swollen by, monomer; (2) post-irradiation grafting—irradiation of dry film *in vacuo* or in air, followed by addition of monomer. These various aspects were described in the papers by Metz *et al.* (Brookhaven), Chapiro (Paris) and Hoffman (Paris). Dr. Chapiro also described the radiation grafting of styrene and methyl methacrylate on to chemically inert polytetrafluoroethylene. Cooper and co-workers compared the graft co-polymers from natural rubber latex and methyl methacrylate using visible, ultra-violet and γ-radiation and measured the effects of changes of monomer concentration and radiation intensity on polymerization-rates and molecular weights. The production of cross-links and of sites for grafting in solid high polymers may be achieved by hydrogen abstraction using ultra-violet light (200–300 mμ). The rate is very much increased by the use of photosensitizers, and a comparative study of this effect with various aromatic carbonyl compounds was described by Oster (Brooklyn). Another method of grafting on to solid polymer was described by Natta (Milan) for poly-α-olefins. These hydrocarbons readily peroxide on heating in air, and the surface or internal hydroperoxide groupings (depending on the nature of the polymer) readily form free radical centres by thermal decomposition.

The mastication of polymers brought into a rubbery state on admixture with monomer causes polymerization of the monomer. This reaction was shown (Watson *et al.*) to have the characteristics of that expected if initiation was brought about by mechanical rupture of the polymer into free radicals. The preparation and properties of block co-polymers of polymethyl methacrylate-polystyrene were described.

Physical, Thermodynamic and Mechanical Properties

In a theoretical paper on rubber elasticity, Flory, Hoeve and Ciferri (Mellon Institute) generalized the rubber elastic equation of state for the case where the chain displays change in internal energy with change in conformation, and investigated the relationship between the temperature coefficient of the mean square end-to-end chain distance $\overline{r_0^2}$ and the elastic equation of state of the network. Gee and co-workers, developing the thesis that the effects of dynamic properties of linear polymers are closely related to intermolecular forces and chain flexibility, reported results on the measurement of the latter properties for poly*iso*butene. A torsion pendulum for measuring the internal friction of polytetrafluoroethylene was described by McCrum (Dupont). Results over the range 4·2° K. to the crystalline melting point at 600° K. indicated that hindered rotation occurs within the crystallites at temperatures as low as 220° K.

Several papers were concerned with the relationships between properties and structure. Meyerhoff and Cantow (Mainz) discussed the molecular weights and molecular weight distribution of branched and unbranched polystyrene, and Magat *et al.* (Paris) extended the theory of the solubility of high polymers to solution of graft co-polymers. Natta discussed the dependence of the properties of α-olefin polymers on their steric composition and summarized extensive results on the physical and mechanical properties of random, stereo and other kinds of block co-polymers.

The technical processes used for the manufacture of polyethylene yield a polymer which shows chain branching, the degree of branching varying considerably with the conditions of polymerization. Methods of measurement of branching have therefore been of paramount interest in characterizing ethylene polymers, and a considerable effort has been expended on these studies. In a detailed and elegant study, Willbourne (I.C.I. Plastics) summarized the preparation of model branched polymethylenes and calibration methods which have been used for developing methods of measuring the numbers and length of branches in polythene. The effect of branching on the degree of crystallinity, crystalline melting point, density, rate of oxidation and dynamic mechanical properties were illustrated and discussed. Gubler and Kovacs (Strasbourg) presented similar physical measurements on a range of commercial polythenes and made an interesting approach to an interpretation of these properties by considering the polymer as a mixture of n-paraffins. The orientation of crystallites which occurs on stretching polyethylene and its dependence on the degree of crystallinity were discussed by R. S. Stein (Amherst), and Eppe, Fischer and Stuart (Mainz) presented results obtained by electron diffraction and electron microscopic studies on the morphological structure of polyethylene, polyamides and other polymers.

The importance of crystallization under stress in fibre-making was emphasized in a paper by Thompson (I.C.I. Fibres), who proposed a model visco-elastic theory to explain the observed results, and de Vries (Amheim) discussed an empirical relationship between draw ratio of synthetic fibres and birefringence.

During the conference a number of technical visits were arranged to commercial laboratories and works. A reception was held on the opening evening, and the conference concluded with a dinner held in the Portland Building of the University.

C. E. H. BAWN

COMPARATIVE ENDOCRINOLOGY

DURING May 25–29, nearly 150 scientists from many parts of the world met at the Cold Spring Harbor Biological Laboratories, Long Island, New York, to take part in the Columbia University Symposium on Comparative Endocrinology. The conference was organized by a committee headed by Prof. A. Gorbman, of the University of Columbia, and the choice of Cold Spring Harbor provided an ideal setting for its deliberations. The scientific programme was split up into a number of sections or main topics.

The first of these was concerned with endocrine factors in ecological adaptation. Prof. W. Hoar (British Columbia) reviewed the role of the endocrine system in permitting fish to survive and adapt themselves to seasonal changes, while his research associate, Miss B. Baggerman, gave neat and conclusive proof of the involvement of salinity preferences in the migratory behaviour of fish.

In his interesting account of mammalian adaptive mechanisms, Dr. J. J. Christian (Bethesda) reported on the relation between adrenal size and population growth in rodents. A gradual numerical increase in the population of mice in cages, without overcrowding, leads to a significant enlargement of the adrenal glands accompanied by lowered reproductive activity (for example, a reduction in litter size), and thus, by inference, to an adjustment of population size. Whether the two phenomena are causally connected is not clear, and it may be that the increased size of the adrenals serves merely as an indicator of population density.

The next session dealt with the endocrine basis of reproductive adaptations in the major groups of vertebrates. Prof. L. Gallien (Paris) described the unusual reproductive habits of *Nectophrenoides orientalis*, a viviparous African frog with a gestation period of nine months. Dr. M. R. Miller (Stanford), in the course of his review of reptilian reproduction, stressed the hazards of inferring endocrine function from morphological study alone. As an illustration he referred to the virtual absence of histologically demonstrable Leydig cells, apparently not associated with androgen deficiency, in certain types of lizard.

In a characteristic contribution, Prof. F. L. Hisaw (Harvard) developed a theory covering vertebrates in general, in which he stressed the ubiquitous, but not necessarily biologically significant, occurrence of progesterone among chordates, and the gradual and independent evolution of luteal and placental function in different mammals, culminating with the largely autonomous placenta of primates.

Both the comparative morphology and physiology of the principal endocrine organs and endocrine function in developing vertebrates received considerable attention during the conference. Prof. E. Wolff (Paris) and Profs. A. Raynaud (Institut Pasteur) and L. J. Wells (Minnesota) reviewed the results of their, by now classical, experiments on somatic or endocrine growth and sexual development in mammalian embryos deprived of either the pituitary or gonads.

In the course of a comprehensive survey, Prof. A. Gorbman (Columbia) directed attention to the vagaries of thyroxine formation in lower vertebrates. Thus, certain types of fish and salamanders form thyroxine from labelled iodine administered to them only after protracted periods (lasting more than a month), while others may not do so at all. Interestingly enough, there is at least one type of frog in which the thyroid gland is completely absent but the larvæ of which none the less undergo metamorphosis.

The inadvisability of applying the results of experiments in mammals to lower animals was also emphasized by other contributors. Prof. B. Houssay (Buenos Aires) and Dr. M. R. Miller (Stanford) reviewed the effects of ablation of both the adenohypophysis and pancreas in different groups of vertebrates, and revealed the following interesting position : while the combined operation in mammals leads to the preparation universally known as the 'Houssay dog', there are important deviations from this situation in lower vertebrates. Thus, birds do not develop hyperglycæmia following removal of the pancreas. On the other hand, in the urodele amphibians (for example, *Triturus*) studied by Dr. Miller, the islet apparatus is of the purely β-cell type and pancreatectomy leads to severe hyperglycæmia. Hypophysectomy, however, does not cause the expected alleviation of the condition until after some months when all inter-renal tissue has atrophied. By contrast, the islets of lizards are of the α-type, and removal of the pancreas induces hypoglycæmia instead of diabetes. Another point established by Dr. Miller is that lizards are highly sensitive to glucagon and insensitive to (mammalian) insulin, in this respect differing markedly from birds.

Similar species differences were also indicated by Dr. S. I. Segal (New York) in the course of a stimulating account which ranged far and wide over the comparative aspects of gonadotrophic action and gonadal function in mammals and birds.

It was no more than a logical step to proceed from this point to a consideration of biochemical variations of hormones among vertebrates, which formed the subject of the next session. Dr. I. I. Geschwind (Berkeley) gave a detailed review of variations in such protein and polypeptide hormones as oxytocin and vasopressin, or the melanophore-stimulating principle of the anterior pituitary, as well as of the methods available for their study. Investigations of this kind may be expected to provide an explanation of the fact that a given hormone preparation such as somatotrophin from one mammalian group may be ineffective in another, or why one hormone (for example, prolactin) may induce wholly different responses in different species.

Neuro-endocrine reflex and co-ordinating mechanisms were the topics of another session. Prof. G. W. Harris (London) discussed the hypothalamic control of thyroid-stimulating hormone secretion, and there were separate accounts of the hormonal requirements for ovulation in amphibia (Dr. C. Y. Chang and Prof. E. Witschi, Iowa), birds (Prof. A. V. Nalbandov, Illinois) and mammals (Dr. J. W. Everett, Duke). The last-named reported in detail on the ability of pituitary autografts to the kidney to become vascularized and resume their functional activity when transplanted near the median eminence of rats. These animals, he indicated, not only resumed œstrous cycles of roughly normal duration but also ovulated, and some, when mated with males, became pregnant. By contrast, transplantation of these grafts to the temporal lobe did not restore cycles.

In a similar context, Dr. K. G. Wingstrand (Copenhagen) referred to experiments in which the adenohypophysis of toads was grafted on the site from which the median eminence had been previously extirpated, and after some weeks resumed its function. This seemed to prove that the anterior lobe must be activated by substances originating in some hypothalamic area other than the median eminence, and that the latter is only a release organ.

Neurosecretion and its role in neuro-endocrine integration were discussed by Profs. E. and B. Scharrer (New York). In their view, many vital processes are not controlled exclusively by either nervous or hormonal mechanisms, but by both. Neither works as a closed system; the neurosecretory cells provide a hormonal link between nervous centres and endocrine glands, whereby their activities are intimately interrelated.

A novel and attractive feature of the conference was a further session devoted to vertebrate organs of an unusual nature or incompletely established endocrine status, such as the ultimobranchial body, Stannius corpuscle, etc. Dr. F. Baker (Columbia), in reviewing the renal thyroid of fishes, described a condition of hyperplasia and aberrant distribution of thyroid follicles of fish kept in water with a low-iodine content. Thyroid masses, developed as a result of such compensatory hypertrophy, may be found in such ectopic sites as the eye, heart and brain, but this can be prevented by transferring the animals to a high-iodine environment.

During the same session, Prof. E. J. W. Barrington (Nottingham) gave a most stimulating and beautifully illustrated account of his bio- and histo-chemical studies on iodine binding in the endostyle of protochordates. He not only showed convincingly that this, indeed, occurs (for example, in amphioxus and tunicates), but also pointed out some interesting theoretical implications of his findings. For example, since iodine binding in amphioxus is associated with the production of an alimentary type of mucus, elaboration of thyroglobulin (which followed phylogenetically later) may have been the outcome of cytochemical evolution, perhaps as an ecological adaptation by chordates to life in fresh water. With regard to the origin of the iodination process, it is of interest that iodine binding also occurs in the surface layer of the tunic of tunicates, possibly as a random binding to scleroprotein. Since, however, the tunic surface is being continually worn away, it is conceivable that the iodination products might, by ingestion, have become incorporated by the animals, at some stage of evolution, into their biochemical processes. This, in turn, may have established the need for a more concentrated and efficient iodination process, and thus have initiated the iodinating function of the endostyle, itself the forerunner of the vertebrate thyroid gland. Although speculative at present, these conclusions may be given a firmer basis by future research.

The increasing use now being made of electron microscopy in the investigation of ultra-structural detail was very evident during the conference. A considerable proportion of contributors had included electron microphotographs, some of the best being those of Dr. J. D. Green (Los Angeles) and Sir Francis Knowles (Marlborough College). The standard of illustrations, in general, was remarkably high. There were many admirable colour slides—few perhaps finer than those shown by Prof. Barrington and Drs. Miller and Knowles. The superb colour film of the rat's ovary during the process of ovulation prepared by Prof. R. J. Blandau (Washington) must also be mentioned in this connexion.

The official proceedings of the entire conference will be issued as a separate volume, publication of which is confidently predicted before the end of the year.

P. ECKSTEIN

GLASGOW UNIVERSITY EXPEDITION TO NORTH RONA AND SULA SGEIR

AN expedition to the remote, uninhabited Scottish islands of North Rona and Sula Sgeir (45 miles north-west of Cape Wrath) took place during June 23–July 23. Arrangements for the expedition were made largely by four members of the University of Glasgow, D. E. Baird, I. O. Macdonald, R. S. Wyburn and S. B. Donald. The other six members of the expedition were Miss Helen C. Nisbet and R. A. Gailey

(University of Glasgow); Mr. and Mrs. M. Lauder-Smith; T. B. Bagenal and H. T. Powell (Marine Station, Millport). The present account refers principally to work carried out on North Rona; one day only was spent on Sula Sgeir.

North Rona is composed of Lewisian gneiss, granulitic in texture and showing strong differentiation into acidic and basic fractions. A notable feature is the occurrence of sheet-like intrusions of quartz–felspar pegmatite with a coarse graphic structure, the outcrops of which are largely controlled by folding along W.N.W.-trending axes. Ample evidence for glaciation exists, but no indication of the direction of ice movement could be found. A thin cover of boulder clay, containing erratics of mainland rocks, exists over most of the island. Remnants of wave-cut platforms were noted, and the approximate heights of the principal morphological features were determined.

The expedition made a detailed ground survey of the remains of Saint Ronan's cell and chapel, the church enclosure, and the adjacent village which has been deserted since 1844. The cell is rectangular with sloping walls and a roof of flat slabs, and may date from the eighth century; the adjoining chapel is later in date and has been used as the village church. The original foundation was probably a hermitage. The village is situated towards the north-west corner of an infield of some 24 acres, cultivated in large lazybeds. There are three groups of ruins in the village, each consisting of a rectangular dwelling surrounded by a number of small circular or oval cells.

A survey of the terrestrial flora was carried out and a collection made of the flowering plants, bryophytes and lichens. Only 44 species of flowering plants were found on North Rona, and Sula Sgeir has only seven. Soils were examined *in situ*, and samples brought back for further study. A comprehensive collection of terrestrial invertebrates was made, and ecto- and endo-parasites were collected from some of the 140 sheep on Rona. Selected blood samples and blood-sucking insects were taken for the Ruchill Virus Research Laboratory.

A survey of the marine flora and fauna was made on both islands and, considering the isolation of the islands and the very severe exposure to swell and wave action, a surprisingly large number of algae and invertebrates was found. One of the rarest and most interesting algae present was *Fucus distichus* subsp. *edentatus*. North Rona is the largest known breeding ground of the Atlantic grey seal, and it is of interest to record that one seal calved successfully as early as July 6; the earliest calves recorded hitherto for Britain have been born in mid-August.

A census was made of the birds breeding on Rona and notes kept of the migrants passing through. Although counts of those species nesting in the sea caves were not always possible, many of the figures obtained show marked changes from the counts made before the War. Leach's petrel was of special interest, for in Britain it breeds on only very few Scottish islands, including North Rona and Sula Sgeir; its distribution and numbers on Rona were estimated, and some 500 were ringed. Of the migrants, the most spectacular was a red-headed bunting that remained on the island for a few days.

Two films and many photographs were taken of features of interest on the islands. The results of the various investigations are now being worked up and will be published elsewhere.

The expedition is grateful to the University of Glasgow, the Carnegie Trust for the Universities of Scotland, Mr. Charles Hepburn, and other individuals, institutions and firms, for financial or other practical support for the venture; to Commander R. C. Dumas and the crew of M.F.V. 289 for invaluable assistance in getting to and from North Rona; and to Dr. R. R. Morrison of Bridge-of-Weir for transporting six members of the expedition from Rona to Sula Sgeir aboard his motor-yacht *Mary Rose of Morar*.

THE INSTITUTE OF PHYSICS

THE thirty-eighth annual report of the Board of the Institute of Physics, covering the work of the Institute during 1957, was presented to the annual general meeting of the Institute on July 1. Particular attention is directed in the report to the steady growth in the membership of the Institute during the past ten years, from 3,455 in 1948 to 5,881 in 1957. The number of applications for election or transfer to the various grades of membership received during the year under review for submission to the membership and examinations committee was 795 compared with 752 in the previous year. Representatives of the committee visited nine technical colleges which had applied for recognition by the Institute. Five colleges requested the recognition of diplomas awarded on full-time or sandwich courses as satisfying the Institute's academic requirements for membership, and two diplomas, the awards of Sunderland Technical College and the Welsh College of Advanced Technology, Cardiff, were accepted. The Board accepted the recommendation of the membership and examinations committee that students following courses in recognized institutions leading to qualifications recognized by the Institute should be eligible for admission to the student grade of membership irrespective of compliance with the Institute's regulations concerning general education, but students who do not comply will still be required to do so before being eligible for the graduateship grade of membership.

In the written papers for the examination for the graduateship grade twenty-one of the sixty-eight candidates satisfied the examiners. There were 542 candidates for the Ordinary National Certificate in applied physics and 182 for the Higher Certificate, compared with 424 and 152, respectively, in 1956.

The circulation, both to members and non-members, of the Institute's two journals, the *Journal of Scientific Instruments* and the *British Journal of Applied Physics*, increased during the year. Supplement No. 6 of the *British Journal of Applied Physics*, containing a selection of the papers presented to the Institute's Non-Destructive Testing Group, including most of those read at the Group's conference held in Bristol in July 1956, was published in May. In the "Physics in Industry" series, a new volume "Pressure Measurement in Vacuum Systems", by J. H. Leck, was published during the year, together with a revised edition of Dr. J. Topping's "Errors of Observation and their Treatment" in the "Monographs for

Students" series. "A Further Handbook of Industrial Radiology" written by fifteen members of the Non-Destructive Testing Group and edited by W. J. Wiltshire, and a fourth selection of "Laboratory and Workshop Notes" reprinted from the 1953–55 *Journal of Scientific Instruments*, compiled and edited by Dr. Ruth Lang, were published by Edward Arnold (Publishers), Ltd., for the Institute.

The third convention of the Institute, held in Oxford during July 10–13, was attended by about 250 members, ladies and guests, a rather smaller attendance than expected. Lectures were delivered by Prof. N. F. Mott on dislocations and the physics of materials and by Prof. A. C. B. Lovell on recent advances in radio-astronomy. The address given by Sir Cyril Hinshelwood on July 11 in the Sheldonian Theatre on "Physics among the Sciences" was published in the September issue of the *Bulletin* (8, 300; 1957) and the lecture by Mr. Alan Bullock on July 12 on "Science and the Humanities" in the December issue (8, 380; 1957).

The Institute has nine branches in Great Britain, a Malayan branch under the chairmanship of Mr. Hon Yung Sen and an Australian branch with divisions in different states under the presidency of Dr. F. W. G. White. The New South Wales division formed a solid-state physics group, the first specialist group to be formed in the Australian branch. In addition to the branches in Great Britain, there are seven specialist subject groups—applied spectroscopy, education, electronics, electron microscopy, non-destructive testing, stress analysis and X-ray analysis—which arrange their own programmes of scientific meetings and conferences.

The Board through its permanent officers has continued to give advice in answer to individual inquiries concerning professional matters, and inquirers requesting assistance in filling vacancies for physicists were advised to advertise in the *Bulletin*, which has now become a recognized medium for this purpose. In reply to the Scientific Manpower Committee of the Government's Advisory Council on Scientific Policy the Board stated that the members of the Board were generally agreed that if the number of graduates in physics were doubled within five to ten years the demand could still exceed the supply, and that the Board was perturbed by the number of first-class physicists who were leaving the country for permanent employment overseas. The results of the fourth survey of salaries and emoluments paid to fellow, associate and graduate members of the Institute were published in the January issue of the *Bulletin* (8, 19; 1957) and reprints were widely distributed. Discussions with the Physical Society for closer collaboration between the Institute and the Society have progressed favourably, and an announcement of interest will shortly be made.

To mark the completion of twenty-five years as secretary and editor, and in recognition of his services to the Institute, a presentation was made by the Board to Dr. H. R. Lang.

At the general meeting of the Institute, the following were elected to take office on October 1: *president*, Sir George Thomson; *vice-president*, Dr. R. W. Sellars; *hon. treasurer*, Dr. J. Taylor; *hon. secretary*, Prof. F. A. Vick. Sir William Lawrence Bragg was elected to Honorary Fellowship.

S. Weintroub

COUNCIL FOR THE PRESERVATION OF RURAL ENGLAND

THE thirty-second annual report* of the Council for the Preservation of Rural England, covering the period May 1957 to April 1958, again stresses the impact which the nuclear power programme is likely to have on the appearance of the countryside. Probably less than a tenth of the population are directly concerned with the land, and it is the urban majority which dictates, in the main, the shape of future developments. The Council welcomes the formation, on Mr. Duncan Sandys's initiative, of the Civic Trust for the encouragement of good architecture and civic planning and the stimulation of interest of urban and suburban dwellers in the visual aspect of town and country and the avoidance of unsightly development. The work of the Council itself continued along the same general lines, but the volume and range of work undertaken continued to increase.

The report provides a very useful summary of the bearing on the preservation of the countryside of recent legislation, such as the Electricity Act, 1957, the Winfrith Heath Act, 1957, the Local Government Bill, the Opencast Coal Bill, the Tribunals and Inquiries Bill and the Water Bill. Considerable discussion and correspondence has taken place between the Council and the Ministry of Housing and Local Government in regard to the recommendations of the Franks report relating to inspectors' reports, and the Ministry has agreed to supply the Council or its branches with copies of such reports on request. The use of land by Service Departments continued to demand much attention, and concern is expressed at the tendency of the Electricity Authorities to adopt the line of least resistance. The protracted negotiations regarding the routing of the electricity supply to the television station on Sandale Fell (Cumberland) are described in some detail as illustrating the meticulous care taken by the Minister of Power to give effect to his undertaking to try to reconcile the claims of landscape beauty with the urgent need to provide electricity in rural areas as economically as possible.

Numerous other instances are cited in the report in which the Council has had to raise objections, and mineral undertakings and roads and footpaths have also been the source of much anxiety, particularly the use of the Kendal to Keswick road over Dunmail Raise by heavy industrial traffic. The Council urges strongly that heavy industrial traffic should be discouraged from using this road by suitable improvements to the west coast road to make this an attractive alternative, and also by developing the alternative route through the Lune valley. This matter is regarded as particularly urgent, and the problem is being thoroughly investigated by traffic experts of the Automobile Association and the Royal Automobile Club.

COLLECTED PAPERS OF THE ROWETT RESEARCH INSTITUTE

THE work done at a large research centre such as the Rowett Institute is necessarily published in a wide variety of journals. It is therefore very helpful when, at regular intervals, a collection of its recent publications becomes available. Volume 14 of the Rowett Institute papers has just been issued*. It contains reprints of more than 60 papers and cites another 30 by title only. Practically all the 94 publications appeared in 1956 and 1957. Several of them will be of interest mainly to the practical man since they deal with subjects of such considerable practical importance as winter grazing in north-east Scotland, methods of extending the grazing season, the rearing of calves and the management of the breeding ewe. A large proportion of the papers, however, are devoted to the valuable basic research work done by the Institute on subjects such as the biochemistry, physiology and microbiology of the rumen, water metabolism in the sheep and energy expenditure in livestock. Some of the other fundamental work described in the collected papers is concerned with the metabolism of short-chain fatty acids and with enzyme studies, particularly work on the glucuronidases.

An important feature of the volume is the fact that it contains a summary extending to 54 pages which is also issued separately from the bound volume and which can be obtained by applying to the Rowett Research Institute. This separate summary begins by giving an account of the history and aims of the Institute, and contains not only a list of all the papers that are collected together in the bound volume with their titles and references, but also a concise account of the work they describe written by the director, Dr. D. P. Cuthbertson. The summary contains also two review articles which are in fact progress reports on two sections of the Institute's work. One deals with glycosidases and their inhibition by aldonolactones and has been written by Dr. G. A. Levvy. The other is a description by Dr. J. Duckworth of the work his Department has been doing on the skeleton in lactation and growth. Both the bound volume and the separate summary can be highly recommended to all who are interested in the recent advances that are now being made, not only in many practical aspects of animal nutrition, but also in the fundamental principles on which the subject is based.

RIBONUCLEOPROTEIN PARTICLES FROM *ESCHERICHIA COLI*

By DR. A. TISSIÈRES and DR. J. D. WATSON

Biological Laboratories, Harvard University, Cambridge, Massachusetts

THE amount of ribonucleic acid in exponentially growing *Escherichia coli* cells with a generation time of about 30 min. is of the order of 25 per cent of the dry weight of the organism. This value varies inversely with the time of generation and seems directly related to the synthetic ability of the cell[1-3]. About 90 per cent of this ribonucleic acid is bound to the ribonucleoprotein particles, which thus form a major constituent of the bacterial cytoplasm. These particles were first described on electron micrographs of *E. coli* lysed by phage[4], and later it was discovered that they contain the bulk of the ribonucleic acid of the cells[5]. They have been found in extracts of all bacterial species so far examined[5,6]. They resemble closely by their size, chemical composition, and several other properties the ribonucleoprotein particles which have been studied in detail in animal and plant tissues[7-10] and in yeast[11], and which are generally believed to be the site of protein synthesis[12,13].

In some animal tissues, such as the pancreas, most of the ribonucleoprotein particles are attached to the reticulum and they can only be isolated after dissolving the membranous material with deoxycholate[8]. In other tissues, however, most of the particles appear to be free in the cytoplasm[14]. The significance of this difference is not known. In bacterial extracts the particles are free. This suggests that they are either free in the cytoplasm or else attached to a very loose structure which collapses when the cells break open.

The early experiments of Schachman, Pardee and Stanier[5] with bacterial extracts indicated the presence of two main fractions with sedimentation constants of 29*S* and 40*S*, which suggested that the bacterial particles might be smaller than those from other sources. Recently, however, several investigators (ref. 15 and personal communication from Spiegelman, S.) have observed the presence of larger particle fractions, characterized by 60*S* and 80*S* when the bacterial extract contained a high concentration of magnesium.

The experiments to be reported here confirm the stabilizing role of magnesium, and indicate that under suitable conditions four types of ribonucleoprotein particles may be observed (32*S*, 51*S*, 70*S* and 100*S*). The 70*S* particle will be shown to break down into the 32*S* and the 51*S* components. Both these smaller units can be obtained in stable conditions, and their properties, as well as those of the 70*S* and 100*S* particles, will be reported and discussed. The sedimentation constants given here were corrected to 20° C. and zero concentration. They are 10–20 per cent higher than those of other workers. This may possibly be explained by the fact that they were measured on isolated particle preparations.

Preparation of Extracts and of Ribonucleoprotein Particles

E. coli strain *B* was grown in broth, at 37° C., under forced aeration. The cells were harvested in the logarithmic phase of growth and washed twice in the refrigerated centrifuge with the buffer used to make the extract. In most cases, the cell-free extract was made by grinding the cells at 4° C. with three parts of alumina powder and extracting with three to six volumes of buffer. Deoxyribonuclease (1γ/ml.) was always added to depolymerize the highly viscous bacterial deoxyribonucleic acid. The procedure for breaking the cells was, however, not critical: extracts made by using sonic vibrations, or by lysing the protoplasts formed following the addition of penicillin to the culture medium[16], gave identical sedimentation patterns.

The crude extract, which is the supernatant after centrifugation at 6,000*g* for 15 min., contains the bulk of the ribonucleic acid of the cells, and only small amounts of it are found in the large cell debris present in the sediment and formed of pieces of cell membranes and cell walls. The supernatant, after centrifuging the crude extract at 100,000*g* for 120 min., contains some low-molecular weight ribonucleic acid in amounts of about 10–15 per cent of the total ribonucleic acid of the crude extract, whereas the major part of this substance is found in the pellet in the form of ribonucleoprotein particles. This pellet is now re-suspended in buffer, and the particles are freed of soluble proteins by successive washings in the centrifuge at 100,000*g*.

Sedimentation Diagrams

When the crude extract is made in 0·01 *M* magnesium acetate and 0·001 *M tris* (hydroxymethyl) aminomethane *p*H 7·4, and the particles from it are resuspended in 0·005 *M* magnesium and dilute *tris*, the schlieren diagram shows a major peak with a sedimentation constant of 100*S*. In addition there is a small amount of a 70*S* peak.

If the particles are resuspended in dilute *tris* containing 0·001 *M* magnesium, there is a major 70*S* peak and small amounts of 32*S*, 51*S* and 100*S* peaks. At a still lower effective magnesium concentration (this is the case with 0·001 *M* magnesium together with 0·01 *M* phosphate buffer, *p*H 7·0) the bulk of the ribonucleoprotein particles is present as 32*S* and 51*S* components. The 70*S* and the 100*S* peaks are not visible. At these magnesium concentrations the transitions are freely reversible, and they can be obtained by dialysis against lower or higher magnesium concentrations. However, at less than 10^{-4} *M* or more than 2 × 10^{2} *M* magnesium, irreversible damage occurs and the particles break down to smaller pieces.

The 32*S* and the 51*S* peaks always appear simultaneously and, as judged by the area under the schlieren curve, the mass of the 51*S* fraction is double that of the 32*S* one. This, together with the fact that the molecular weight of the 32*S* particle is probably half that of the 51*S* one (see below), would indicate that each 70*S* particle is formed of one 51*S* and one 32*S* component. The relation between 70*S* and 100*S* particles is most likely a monomer–dimer transition. Electron micrographs of 100*S* preparations show large numbers of spherical particles in groups of two, whereas 70*S* preparations reveal a majority of isolated spherical bodies (Dr. C. Hall, personal communication).

Isolation of the 51S Component

The crude extract, prepared in 0·01 *M* phosphate buffer *p*H 7·0 and 0·001 *M* magnesium, is centrifuged at 100,000*g* for 120 min. The supernatant containing the soluble proteins is poured off, and the pellet is resuspended in the same buffer. This is now centrifuged at 100,000*g* for 90 min., the supernatant is poured off, and the pellet is resuspended as above. This step is repeated twice. Finally, the preparation is brought to *p*H 5·0 by addition of 0·1 *N* acetic acid and it is centrifuged for 30 min. at 20,000*g*. The supernatant is collected and neutralized with dilute ammonia. The 51*S* preparation thus obtained is pure according to the following criteria: (1) it shows only one peak in the centrifuge; (2) it moves as a single peak in the electrophoresis apparatus between *p*H 4·7 and 7·6; (3) it shows only one kind of particle on electron micrographs (Dr. C. Hall, personal communication).

Isolation of 70S–100S Components

The crude extract was made with 0·01 *M* magnesium ion and 0·001 *M tris* buffer. Under these conditions the 32*S* and the 51*S* peaks are not visible on the sedimentation diagrams, and the 100*S* peak is higher than the 70*S*. This extract is then centrifuged at 78,000*g* for 120 min. The supernatant is poured off and the pellet, which is much larger than that obtained when the extract is made in phosphate, is resuspended in *tris* buffer and 0·005 *M* magnesium acetate. The mixture is centrifuged again at 78,000*g* for 120 min. This last step is repeated twice, and finally the pellet is resuspended in *tris* containing 0·002 *M* magnesium and centrifuged at 15,000*g* for 30 min. The 32*S* and the 51*S* peaks are not detectable in the supernatant. There is mostly a 70*S* peak with, in addition, 10–20 per cent of a 100*S* peak.

Properties of the Particles

Chemical composition. Ribonucleic acid and protein estimations were carried out on the purified preparations by the orcinol[17] and biuret[18] methods respectively, together with determinations of dry weights. Both the 51*S* and the 70*S*–100*S* particles were found to contain 60–65 per cent of ribonucleic acid and 40–35 per cent of protein. In each experiment the dry weight amounted to the sum of the weights of ribonucleic acid and protein within 1 or 2 per cent. Thus the particles are formed mostly, if not exclusively, of ribonucleic acid and protein.

The density of the 32*S* particles is the same as that of the 51*S*: both components sedimented at the same relative rate in a sucrose solution with a density of 1·25 as in 0·01 *M* phosphate. Thus it is likely that the four components are formed of ribonucleic acid and protein in the same proportion.

Are enzymes present in the particles? The results available are quite insufficient to decide this point. In bacterial preparations some respiratory enzymes have been found in the small-particle fraction rich in ribonucleic acid[19,20]. However, it has recently been reported that purified ribonucleoprotein particles are free from these enzymes[21]. We made the same observation: the reduced diphosphopyridine nucleotide oxidase activity disappears during the purification of the particles and the pure preparations are free from this enzyme system. The results show that the particles supporting the oxidizing enzymes are not homogeneous in size. This indicates that they are probably derived from a larger structure which breaks down to small pieces when the bacterium bursts open. It is likely that this structure is the cell membrane.

Stability in various conditions. The 51*S* and 70*S*–100*S* components are remarkably stable provided the required amount of magnesium is present. They are stable for more than two months in the cold in the presence of streptomycin or in the frozen state. The 51*S* preparation is stable for 24 hr. at *p*H 5·0 or 9·0, whereas the 70*S*–100*S* components break down under these conditions. If the magnesium concentration is lowered, or if ethylenediamine tetraacetate is added, the 51*S* particles initially break down into two components of 42*S* and 18*S*. The 32*S* component does not appear during this process. All four kinds of particles are affected irreversibly by salt concentration of the order of 0·1 *M*.

1–5 μgm./ml. of ribonuclease, at *p*H 7·6, had no effect on most 51*S* preparations, as judged by the appearance of the peak in the analytical centrifuge. In a few cases, however, the 51*S* peak disappeared after this treatment. This indicates that the particles can exist in somewhat different states. Generally, both the 32*S* and the 70*S*–100*S* particles were more sensitive to the action of the enzyme, but the rate at which they were affected was always considerably slower than would be the case with pure ribonucleic acid.

Sedimentation and diffusion constants. The sedimentation constants of all four components were measured both with the schlieren and the ultra-violet optics, with concentrations varying from 2 mgm./ml. down to 40 μgm./ml. In most cases, the values fell within about 2 per cent of those given above. Under these conditions the dependence on concentration was no more than 5 per cent. The salt concentration had no appreciable effect between 0·01 and 0·05 *M* phosphate and 0·001 and 0·05 *M tris* buffer.

The diffusion constant, $D_{20} \times 10^7$, of the 51*S* component was found to be 1·98. It was independent of the concentration between 0·07 and 0·20 per cent. The partial specific volume, measured with a 25-ml. pycnometer, was 0·66. Thus the molecular weight of the 51*S* particles is $1 \cdot 85 \times 10^6 \pm 10$ per cent.

The molecular weight of the 32*S* particles is about $9 \cdot 5 \times 10^5$, which is half that of the 51*S* component. This value is based on the sedimentation constant together with a rough estimation of the diffusion constant by following the spreading of the boundary during centrifugation. Thus, the molecular weight of the 70*S* component, which appears to be formed of one 32*S* and one 51*S* particle, is approximately $2 \cdot 8 \times 10^6$.

Similarity of the Bacterial, Animal and Plant Ribonucleoprotein Particles

The reversible breakdown of the 70*S* particles to the 32*S* and 51*S* components parallels the behaviour of other ribonucleoprotein particles. In both yeast[22] and pea seedlings[10], 80*S* particles break down reversibly to 60*S* and 40*S* units. It is likely that these experiments express a general phenomenon: the presence of a principal ribonucleoprotein particle of 70–80*S* and its construction from two unequal units, one twice the mass of the other.

The sedimentation constant of the 70*S* component is lower than the values given for liver (77·5*S*)[9], pea seedling (74*S*)[10], and yeast particles (80*S*)[11]. The chemical composition reported in the literature varies. For example, about 40 per cent ribonucleic acid is found in pea seedlings[10], liver[9] and yeast particles[11], whereas in the rabbit appendix they contain 65 per cent ribonucleic acid[23].

If the molecular weight of the 70*S* component is $2 \cdot 8 \times 10^6$, the ribonucleic acid content in molecular weight units is about $1 \cdot 7 \times 10^6$. This figure is very similar to that calculated for yeast and plant particles on the basis of a molecular weight of 4×10^6 and a ribonucleic acid content of 40 per cent. Thus it may be that the amount of ribonucleic acid in the particles is fairly constant, whereas the amount of protein can vary with the origin of the cells.

Summarizing, we conclude that:

(1) The ribonucleoprotein particles from *E. coli* are very similar to those of yeast, plant and animal cells. (2) For stability they need the presence of magnesium ions, and the requirement of the bacterial particles seems greater than that of particles from other sources. (3) On varying the magnesium concentration four different kinds of particles are observed with sedimentation constants of 32*S*, 51*S*, 70*S* and 100*S*. (4) The 70*S* particle is formed of one 32*S* and one 51*S* component. (5) The 100*S* particle is an aggregate of two 70*S* components. (6) The four kinds of particles appear to have the same chemical composition: they contain 60–65 per cent ribonucleic acid and 40–35 per cent protein. (7) The molecular weight of the 51*S* component is $1 \cdot 85 \times 10^6 \pm 10$ per cent; those of the 32*S* and 70*S* units are approximately $0 \cdot 95 \times 10^6$ and $2 \cdot 8 \times 10^6$ respectively. (8) The particles are relatively stable to ribonuclease.

We wish to thank Dr. J. T. Edsall for his encouragement and for the use of the analytical centrifuge, Miss B. Hollingworth for diffusion and electrophoresis measurements, and Dr. D. M. Skinner for her assistance in some of these experiments. We are also indebted to Dr. S. Spiegleman for supplying us ultracentrifuge data on his particle fractions. The work has been supported by a grant from the U.S. National Science Foundation.

FOLLICLE ARRANGEMENT IN SKIN FROM WILD SHEEP, PRIMITIVE DOMESTIC SHEEP AND IN PARCHMENT

By Dr. M. L. RYDER

Biology Department, Wool Industries Research Association, Torridon, Headingley, Leeds 6

RYDER[1] showed that in the Mouflon the secondary follicles were between the primaries instead of lying more towards one side of them, as they commonly do in many animals and in highly evolved domestic sheep. Skin has now been examined histologically from each of the main types of wild sheep, namely, Bighorn (*Ovis canadensis*), two varieties plus one unknown; Argali (*O. ammon*), three plus one unknown; Urial (*O. orientalis*), two plus two unknown; and Mouflon (*O. musimon*), three specimens.

In addition, skin has been examined from Mouflon × Soay, Soay, Shetland, a hairy West African sheep, an English and a Nigerian domestic goat, and a Barbary lamb (*Ammotragus lervia lervia*). Although much of the skin was from dried museum specimens, good preparations have been obtained, Sandison's[2] softening fluid being helpful, as it was with parchment.

All the wild sheep (Fig. 1) had secondaries between the primaries, and the primaries were in straight lines, in trios or often in groups of five. The follicles were disposed at much more acute angles than in domestic sheep, and there was an extremely large difference in diameter between the primary and secondary fibres. The primaries were coarser than the coarsest fibres of domestic sheep, while the secondaries were as fine as the finest Merino.

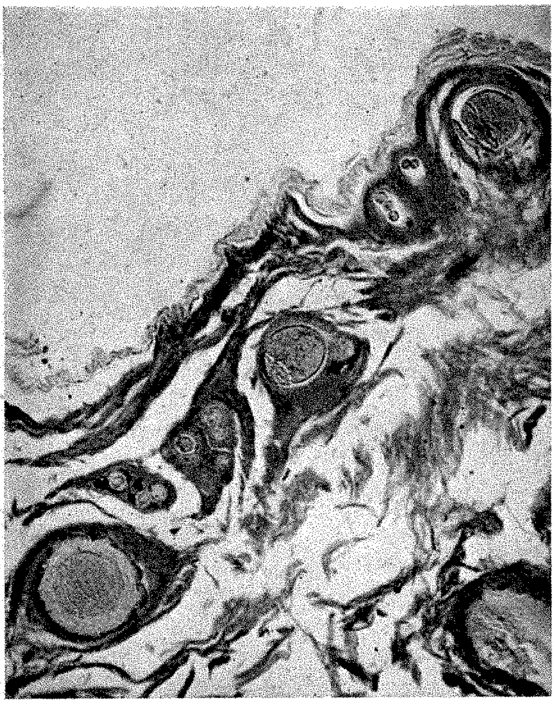

Fig. 1. Horizontal section of Urial sheep skin showing smaller secondary follicles between the primaries. (× 140)

The 'hairy primitive' domestic sheep have a large difference in diameter between the primaries and secondaries; the Black Headed Persian depicted by Duerden[3] had a strong tendency for the secondaries to lie between the primaries, and the same arrangement was found in a sheep skin from the Cameroons, believed to be from the West African Dwarf. In these, therefore, the secondaries seem to be beginning to move from between the primaries.

The Soay, a 'woolly primitive' domestic type, had clear primary trios, appreciable difference in diameter between the primaries and secondaries, and the secondaries were grouped in two wedges, only the points of which were between the primaries (Fig. 2*e*). Such an arrangement is often found in the Scots Blackface, whose latticed medullæ make it somewhat similar to the hairy group. The arrangement in the Mouflon × Soay (Fig. 2*c*) was similar to that of the wild sheep, having apparently reverted to the more primitive condition. But the primary fibres were not as coarse and did not have latticed medullæ. The Shetland had an arrangement similar to that of the Soay, but the fibres were on the whole finer, and there was less difference in diameter between the primaries and secondaries (Fig. 2*d*).

The evolutionary trend seems, therefore, to have been a movement of secondaries from between the primaries accompanied by a tendency for the primaries to move closer together and to lie on an arc. As more secondaries have developed in finer-woolled types, these have spread away from the primaries. The goat's arrangement was similar to that of the hairy domestic sheep (Fig. 2*a*) and their coats are not dissimilar. The lattices of the goat medullæ were, however, smaller and more regular than in sheep. It is interesting that the Barbary (Fig. 2*b*) was like the goat, because it suggests that the genus *Ammotragus*, considered to be intermediate between *Ovis* and *Capra*, shows, so far as follicle arrangement is concerned, greater affinity to goats than sheep.

Previous work on the ancestry of domestic sheep has neglected the skin. However, these results obtained with dried skin suggested that the examination of ancient material might provide a useful new approach. Good preparations were obtained from the skin of an ancient Egyptian mummified cat, so it would seem worth while examining any skin that is available from mummified sheep. Few follicles were found in leather, but excellent preparations were obtained from parchment. Fewer follicles were found in modern than in ancient parchment, possibly owing to the greater efficiency of the modern de-hairing process. Samples of parchment are difficult to obtain, and the only ones examined so far are: a specimen from some Aramaic documents of the fifth century B.C., which, however, are leather[4]; eighteen specimens from the Dead Sea scrolls, generally considered to be of about the time of Christ; five specimens of about A.D. 150 from the nearby

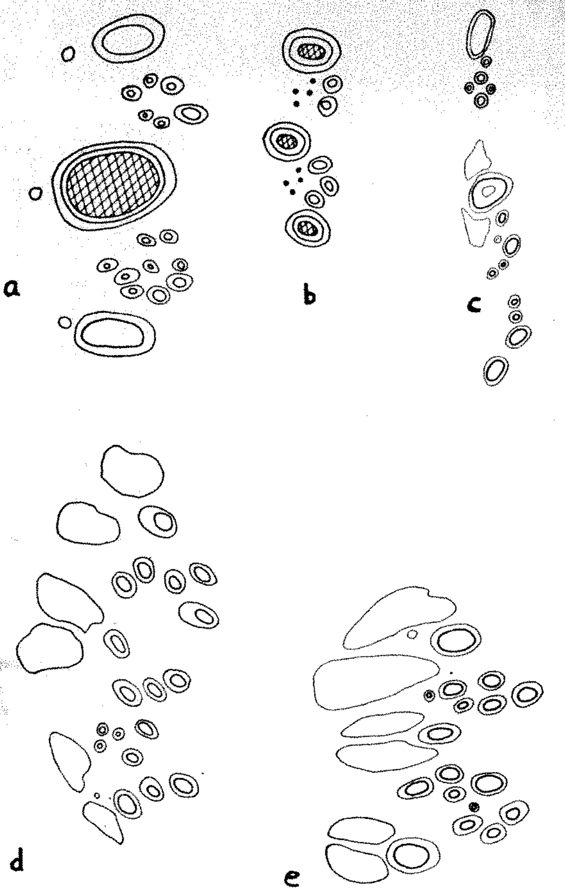

Fig. 2. Diagrams prepared from projection microscope tracings of follicle groups (ectal margin to right) from (*a*) goat; (*b*) Barbary lamb; (*c*) Mouflon × Soay; (*d*) Shetland; (*e*) Soay. Developing follicles in full black, latticed medullæ cross-hatched. Where visible, sebaceous glands have been indicated by irregular outlines and sweat glands by simple circles. Barbary lamb (× 82); others (× 41)

excavations at Murabba'at; and a sample of an English parchment dated 1692.

The histological structure of the follicles was remarkably well preserved and nuclei were often visible, although there had been some changes in staining reaction. The present description will, however, be restricted mainly to follicle grouping. This was perfect in only two Dead Sea scroll samples and two from Murabba'at, one from each of the three types of sheep found, namely, hairy, medium-woolled and fine-woolled, and a calf. All the samples showed traces of follicles, and as all but one had fibres, their type could usually be ascertained. The hairy type had large primaries with groups of small secondaries wedged between them (Fig. 3*a*). It is difficult to say whether this is from a sheep or a goat, but the secondary/primary ratio of about 4/1 suggests sheep rather than goat, which has a ratio of about 2/1. Three other samples, including one from Murabba'at, had both large and small follicles and were probably of this type.

The medium-woolled type (Fig. 4) had an arrangement similar to that of the Soay, with an appreciable difference in diameter between the primaries and secondaries, and a secondary/primary ratio of about 5/1. The fibres were non-medullated and had an irregular mosaic scale pattern, which in places approached the diagonal pattern characteristic of lustre (long-woolled) types; this is not found in the Soay. Five other scroll samples and one from Murabba'at had fibres of a similar diameter, and at least three had this diagonal scale pattern.

The fine-woolled type was most striking (Fig. 3*b*); it had large follicle groups with a secondary/primary ratio of more than 7/1. Such a high ratio and small fibre diameter are uncommon in modern British sheep, and this together with the characteristic scale pattern of fine wool suggests Merino type, which has been thought to originate in the Middle East. There were two other samples with fine fibres and the same scale pattern; a further four samples appeared to be coarser than this type, yet not as coarse as the medium type, and three samples, including one from Murabba'at, although apparently sheep, could not be classified. Two samples identified as calf, one from the scrolls and one from Murabba'at, were the only ones showing pigment.

The Aramaic documents have so far shown no clear groups; but traces of large follicles have been seen, as well as fine fibres, again suggesting a hairy type.

The English parchment of 1692 had fibres as fine as the fine type above, but the groups were smaller.

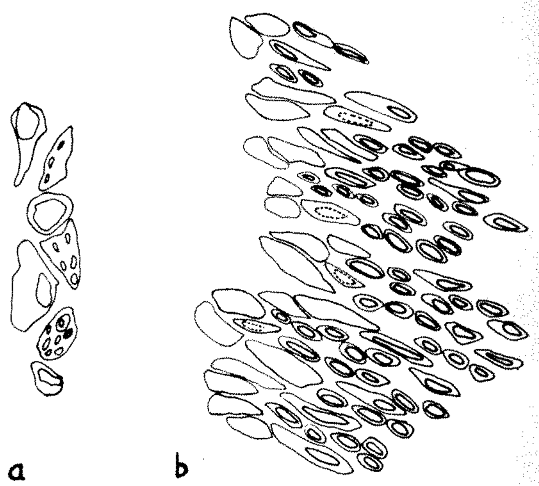

Fig. 3. Tracings of follicle groups in parchment from the Dead Sea scrolls: (*a*) hairy sheep or goat; (*b*) fine-woolled sheep (× 55)

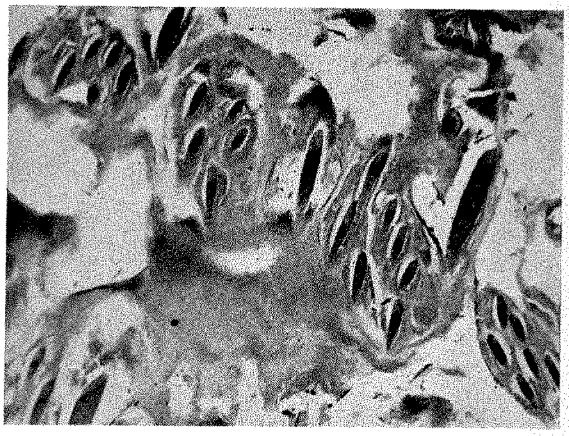

Fig. 4. Follicle group from medium-woolled sheep in parchment sample from Murabba'at (× 63)

Plug-like bodies were seen, suggesting either developing or shedding follicles; developing follicles would indicate a lamb. The fibres were finer than those of a modern day-old Romney lamb, and many of the follicles, but apparently none of the fibres, were pigmented.

It is hoped that these striking findings will stimulate the provision of material by libraries and museums, so that a more extensive study can be made, when the relation of these findings to the domestic evolution of sheep will be discussed.

I wish to thank the authorities of the British Museum (Natural History) and the Royal Scottish Museum for skin samples, Dr. A. T. Sandison for the material from a mummified cat, and Mr. W. N. Beesley for bringing a skin from the Cameroons. I am indebted to Prof. Donald Burton, Dr. R. Reed and Mr. J. B. Poole, of the Department of Leather Industries, The University, Leeds 2, for providing the material from the Dead Sea scrolls and Murabba'at and the other leather and parchment samples. My thanks are also due to Mr. G. R. Standley and Miss M. M. Vickers for technical assistance.

SALT GLANDS IN MARINE REPTILES

By KNUT SCHMIDT-NIELSEN
Department of Zoology, Duke University, Durham, North Carolina
AND
RAGNÄR FANGE
Zoophysiological Institute, University of Lund, Sweden

"SO they went up to the Mock Turtle, who looked at them with large eyes full of tears"[1]; " 'for I am the Crocodile,' and he wept crocodile-tears to show it was quite true"[2]. Frequent literary references to a propensity for tear production in reptiles have not sufficiently challenged scientific imagination, and an interesting chapter in the physiology of excretion has remained unnoticed.

The finding that marine birds depend on a gland in the head rather than the kidney for the excretion of salt[3] [4] suggested an investigation of their reptilian relatives, the marine turtles, crocodiles, snakes and lizards. These animals have maintained the terrestrial habit of air-breathing, and have an integument practically impermeable to salt and water. In these respects their physiology is essentially that of a terrestrial animal, but an important difference is that their food often has a high salt content, and the only drinking water available contains 3·5 per cent salt. Thus, their problems of osmo-regulation are comparable to those of marine birds.

Marine birds can tolerate the ingestion of sea water because the salt gland can excrete sodium chloride in a concentration almost twice as high as in sea water. Thus, marine birds do not suffer from the intake of sea water, in spite of the inability of their kidney to produce a urine more than about half as concentrated as sea water. The concentrating ability of the reptilian kidney is even lower, and marine reptiles could therefore be expected to have a mechanism for salt excretion similar to that in marine birds.

Marine reptiles. Reptiles with a marine habitat are found in four different orders: turtles, crocodiles, snakes and lizards.

Five species of turtles are strictly marine, going on land only to lay their eggs in the sand of tropical beaches. Their food consists of fish, some invertebrates, or seaweed. While the fish have a relatively low salt content, invertebrates as well as seaweed have the same osmotic concentration as sea water. These latter types of food, therefore, impose a heavy burden on the processes of osmo-regulation. Other turtles are found in brackish water, such as the diamond-back terrapin, *Malacolemys terrapin*. This animal is never found in truly fresh water[5].

One species of crocodile, the salt water crocodile (*Crocodylus porosus*), is estuarine in its habits, but has occasionally been found far out at sea in the Indian and Pacific Oceans. It is a carnivore, subsisting mainly on fish.

The sea-snakes, Hydrophidae, are common in the Indian Ocean. Some of the more primitive (*Laticauda*) lay their eggs on land, while the more specialized bear living young. They are all excellent swimmers and live on fish. Probably many other snakes are able to live in brackish water, an example being *Natrix sipedon compressicauda*, which is reported from brackish swamps in Florida[5].

One lizard, the Galapagos sea iguana (*Amblyrhynchus cristatus*), is well known for its appearance as well as its habits. It lives in the surf of the Galapagos Islands, where it climbs on rocks and eats seaweed exclusively[6]. A few other lizards also have been reported from a marine habitat[5].

Head glands. Several different kinds of head glands are found in the four reptilian orders mentioned. There are glands in the orbit of the eye (Harderian gland and lachrymal glands), glands opening into the nasal cavity (nasal glands), and glands opening into the mouth (salivary glands, poison glands, etc.).

In order to find whether marine reptiles are provided with salt glands we used two approaches, studies of (1) the histological structure of the head glands, and (2) the secretion obtained after a salt load, or after stimulation of the glands with the drug methacholine, a drug which stimulates glandular secretion in general.

Turtles have a large gland on each side of the head, located in the orbit of the eye. In the logger-

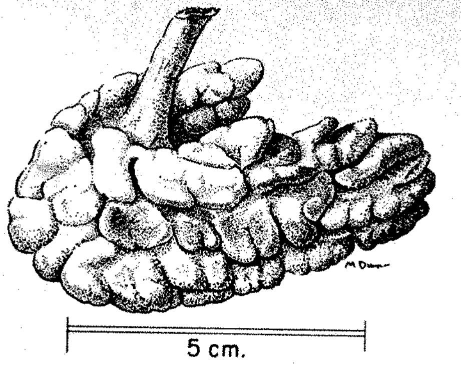

Fig. 1. Salt gland of the loggerhead turtle, *Caretta caretta*

head turtle, *Caretta caretta*, this gland (Fig. 1) is large, reddish-brown, and divided into about one hundred lobes separated by blood vessels and connective tissue. It connects to the exterior via a short, wide duct that opens in the posterior corner of the eye. The two glands weighed 60 gm. in a turtle of 130 kgm., which is 0·05 per cent of the body-weight. The relative weight of the gland was similar in the diamond-back terrapin. In the herring gull we have found the salt gland to be almost 0·1 per cent of the body-weight, and in the brown pelican 0·03 per cent.

The loggerhead gland consists of closely packed branching glandular tubules (Fig. 2) radiating from central ducts or canals in the lobes. This characteristic histological structure, which has previously been observed in the large 'lachrymal' gland of *Chelonia mydas*[7], is similar to the structure of the avian salt gland[8]. The structure of the terrapin gland is similar but less regular.

Crocodiles have well-developed nasal and Harderian glands[9,10], but the functions of these glands are not known. The nasal gland in *Crocodylus porosus* has been described as a rather large acinous gland[11].

Several sea-snakes, for example *Enhydris*, have a well-developed nasal gland[12]. It is, however, missing in one sea-snake, *Pelamis*. According to our own observations on a sea-snake (*Hydrophis ornata*) there is a gland above the eye with a histological structure resembling that of the salt gland of the terrapin. The gland consists of closely packed glandular tubules.

The marine iguana has a large nasal gland which in a specimen of 490 gm. weighed about 300 mgm. (0·06 per cent of the body-weight). Histologically the structure of this gland resembles that of the avian salt gland. The gland opens, via a short duct, into the lateral nasal cavity, which seemingly can function as a reservoir for the secretion. A ridge prevents the secretion from flowing back into the posterior part of the nasal cavity, from where it would drain into the œsophagus. On the other hand, a sudden expiration of air would force the liquid out through the nostril.

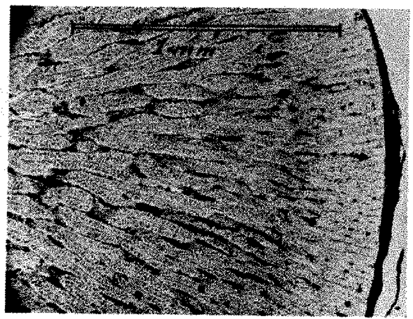

Fig. 2. Microscopic structure of salt gland of the loggerhead turtle

Secretion from salt glands. Marine turtles, when given an injection of hypertonic sodium chloride, secrete a highly concentrated salt solution from the orbital salt gland. This we could demonstrate in the diamond-back terrapin (*Malacolemys terrapin*), a brackish water turtle from Florida, which, when given 10 ml. of 10 per cent sodium chloride per kgm. body-weight, secreted a fluid which appeared as 'tears' in the eye. The sodium concentration of this fluid was 616–784 m.equiv. sodium/l. This salt concentration is well above that of sea water (about 500 m.equiv. sodium/l.).

In a large specimen of the completely marine loggerhead turtle, the duct of the salt gland was easily cannulated, and it could be established with certainty that the secretion came from this particular gland. Samples of secretion obtained after salt load and stimulation with methacholine contained 732–878 m.equiv. sodium/l., 810–992 m.equiv. chlorine/l. and 18–31 m.equiv. potassium/l. These concentrations are similar to those produced by the salt gland of marine birds.

The fact that turtles cry tears when they go on shore to lay their eggs has received much attention. The anthropomorphic interpretation that the tears are induced by the pain of egg-laying has been rejected by naturalists, who instead have speculated that they may serve to keep the eyes from drying out, or to keep the sand out. The latter obviously is not compatible with the descriptions such as that given by Carr[13]: "The curious 'crying' by nesting females (apparently a device to keep the eyes washed free of sand) has been noted in other species. The present turtle began secreting copious tears shortly after she left the water, and these continued to flow as the nest was dug. By the time she began to lay, her eyes were closed and plastered over with tear-soaked sand and the effect was doleful in the extreme".

It may instead be suggested that the turtle tears are produced in response to the osmotic load of living and feeding in the sea, and that their major role may be osmo-regulatory.

We had no opportunity to work with living specimens of the salt-water crocodile, nor with living sea-snakes. One water snake, the Mangrove water snake (*Natrix sipedon compressicauda*), which is a sub-species of the common water snake, showed no secretion from head glands when given a salt load. Stimulation with methacholine gave only slight secretion from mucous glands. We did not find any glands in the head of *N. s. compressicauda* that could be interpreted anatomically as salt glands.

The marine iguana has repeatedly been observed to blow out "a thin shower of water vapour" from the nostrils[14]. We induced secretion in two animals that had been kept in captivity for three months, by the injection of sodium chloride (10 ml. of 10 per cent solution per kgm. body-weight) and methacholine. The secreted fluid was ejected from the nostrils as fine drops.

When picking up a lizard one of us was hit in the face and eyes with a jet of droplets that had a salty taste. This rather subjective observation of a high salt content was followed by a more accurate

SOME NEW BOOKS
FROM OXFORD

ESP and Personality Patterns

GERTRUDE RAFFEL SCHMEIDLER AND
R. A. McCONNELL

With a Preface by GARDNER MURPHY

A report on the relation between personality and extrasensory perception. It reviews published laboratory evidence for ESP as a statistical phenomenon, and makes the first conclusive presentation of nine years of experimental research. YALE UNIVERSITY PRESS 25*s. net*

The Physics of Rubber Elasticity

L. R. G. TRELOAR

The main object of this book (first published in 1949) is to present the statistical theory of rubber elasticity in a form in which its underlying physical concepts may be readily grasped, and to show how this theory provides a natural interpretation of the main physical phenomena associated with rubberlike materials. (MONOGRAPHS ON THE PHYSICS AND CHEMISTRY OF MATERIALS) *Second edition* 40*s. net*

Nuclear Structure

LEONARD EISENBUD AND
EUGENE P. WIGNER

The authors' purpose is to acquaint the reader with the problems of nuclear structure and to outline the proposed solutions, to guide him in his choice of a subject for more specialized study, and to aid him in his search for more detailed expositions. PRINCETON UNIVERSITY PRESS 25*s. net*

Structure and Evolution of the Stars

MARTIN SCHWARZSCHILD

The methods used in the many new investigations and the results thus far obtained are here considered in a single volume, and a summary is given of the present status of the theory of stellar evolution. PRINCETON UNIVERSITY PRESS 48*s. net*

Seals, Sea Lions and Walruses

A Review of the Pinnipedia

VICTOR B. SCHEFFER

This is a zoological survey of all pinnipedia, of which there are thirty-one species and sixteen subspecies; it is the only complete work of its kind. STANFORD UNIVERSITY PRESS *Illustrated* 30*s. net*

A History of Magic and Experimental Science

Volumes VII and VIII:
The Seventeenth Century

LYNN THORNDIKE

These two volumes deal with the development of experimental science during the seventeenth century and the rich residue of the occult down to Sir Isaac Newton, 'the last of the magicians'. COLUMBIA UNIVERSITY PRESS. *Each volume* £4 *net*

UNIVERSITY PRESS

ATOMS FOR PEACE · GENEVA 1958

The "Presentation Set" given to official delegates at Geneva by the U.S.A.

JUST PUBLISHED by Addison-Wesley

PROJECT SHERWOOD—The U.S. Program in Controlled Fusion
By Amasa S. Bishop, *U.S. Atomic Energy Commission*

The first detailed account of "Project Sherwood"—the search for means of harnessing the energy of thermonuclear reactions. Written for the thoughtful layman as well as for scientists and engineers, this book parallels the historic "Smyth Report." 228 pp., 53 illus., 1958—$5.75

U.S. RESEARCH REACTOR OPERATION AND USE
Edited by Joel W. Chastain, Jr., *Battelle Memorial Institute*

Describes the basic types of research reactors, and the uses for which each is best suited; also discusses operating, administrative, legal and cost problems. 384 pp., 181 illus., 1958—$7.50.

RADIATION BIOLOGY AND MEDICINE: Selected Reviews in the Life Sciences
Edited by Walter D. Claus, *U.S. Atomic Energy Commission*

More than 50 distinguished authors review advances in the uses and effects of nuclear radiation in biology, medicine, and agriculture. Among the topics covered are radioisotopes in medicine and agriculture, mutations, permissible dosages, and mathematical biology. 968 pp., 198 illus., 1958—$11.50

URANIUM ORE PROCESSING
Edited by J. W. Clegg and D. D. Foley, *Battelle Memorial Institute*

For the first time in book form, a condensed but essentially complete description of current practices in the winning of uranium from its ores. 450 pp., 118 illus., 1958—$7.50.

THORIUM PRODUCTION TECHNOLOGY
By F. L. Cuthbert, *National Lead Company of Ohio*

Contains virtually all of the information currently available on thorium production technology. The organization of the book follows the natural production flow from minerals in the ground to the fabricated slug. 320 pp., 84 illus., 1958—$6.50.

SOLID FUEL REACTORS
By J. R. Dietrich and W. H. Zinn, *General Nuclear Engineering Corporation*

Reviews the basic concepts, present state of development, and technical and economic outlooks of five projected solid fuel nuclear power reactor types; fast-neutron power breeders, heavy-water reactors, gas-cooled reactors, organic moderated and cooled reactors, and a thermal reactor for recycling plutonium. 864 pp., 385 illus., 1958—$10.75

PHYSICAL METALLURGY OF URANIUM
By A. N. Holden, *General Electric Company, Vallecitos Atomic Laboratory*

A comprehensive and unified treatment which places emphasis upon interpretation in terms of fundamental properties and mechanisms, and relates the metallurgical behavior of uranium to that of other metals. 272 pp., 190 illus., 1958—$5.75

BOILING WATER REACTORS
By Andrew W. Kramer, *Editor,* Atomics, *and formerly Editor,* Power Engineering.

This valuable reference work on the history and technology of boiling water reactors includes detailed descriptions of the Experimental Boiling Water Reactor (EBWR), the Vallecitos reactor, and the various BORAX experiments. 592 pp., 292 illus., 1958—$5.80

FLUID FUEL REACTORS
Edited by J. A. Lane and H. G. MacPherson, *Oak Ridge National Laboratory,* and Frank Maslan, *Brookhaven National Laboratory.*

A thorough treatment of three basic types of fluid fuel reactors: aqueous homogeneous reactors, fused salt systems, and liquid metal fuel reactors. 1008 pp., 338 illus., 1958—$11.50

THE TRANSURANIUM ELEMENTS
By Glenn T. Seaborg, *University of California*

This book provides a complete summary of the chemical and nuclear properties of the known synthetic transuranium elements, as well as the prospects for future elements. 354 pp., 73 illus., 1958—$7.00.

SODIUM GRAPHITE REACTORS
By Chauncey Starr and R. W. Dickinson, *Atomics International*

A unified and coherent presentation of sodium graphite reactor technology. While emphasis has been placed on the design and development of the Sodium Reactor Experiment (SRE), the authors have wherever possible included information applicable to sodium graphite systems and, in many cases, to reactor design in general. 304 pp., 99 illus., 1958—$6.50

THE SHIPPINGPORT PRESSURIZED WATER REACTOR
Written by personnel of the Naval Reactor Branch, Division of Reactor Development, U.S. Atomic Energy Commission; Westinghouse Electric Corp., Bettis Plant; and Duquesne Light Company

A complete account of the first large-scale central station nuclear power plant to be built and operated in the western hemisphere, written by the scientists and engineers who designed, developed, constructed, and tested the plant. 600 pp., 163 illus., 1958—$9.50

Special price for complete set of 12 volumes—$84.00. *These prepublication prices good only until December 1, 1958*

Available in the British Isles from ACADEMIC BOOKS LTD., 129 Queensway, London, W.2

ENZYMES

M. DIXON, M.A., Ph.D., Sc.D., F.R.S.,
and E. C. WEBB, M.A., Ph.D.

This is a much needed authoritative and up-to-date textbook on the study of enzymes. It deals comprehensively with general principles, and, much of the material appears in print for the first time—in particular the only complete table of well authenticated enzymes (nearly 700) with their relations and the most useful references for each.

"Dr. Dixon and Dr. Webb have provided what is probably the best and most compact guide yet published ; it is one for research workers and students . . ."

(from an article in THE TIMES)

With diagrams. 90s. net.

SPECIAL THEORY OF RELATIVITY

G. STEPHENSON, B.Sc., Ph.D., D.I.C.,
and C. W. KILMISTER, M.Sc., Ph.D.

An up-to-date account of the special theory of relativity, it is suitable for students pursuing an honours degree course in physics or mathematics, and contains a large number of applications of interest to the research physicist and electrical engineer.

With diagrams. 18s. net.

THE ELECTRICAL & MAGNETIC PROPERTIES OF SOLIDS

N. E. CUSACK, B.Sc., Ph.D.

This book, written by a University teacher and research worker, for students reading a degree in Physics, and for those just beginning postgraduate research, describes the important electrical and magnetic properties of solids—both those long-established and many recently discovered—and explains them within the context of contemporary solid state physics. There are very many references to the specialist literature.

R. TECWYN WILLIAMS

THE PURPOSE OF the journal is to bring together in one medium papers dealing with toxicology in a wide range of scientific disciplines. Toxicology in its broad sense includes the effect of chemicals, drugs, pharmaceutical preparations, and natural products on plants, animals, and man. A portion of the journal will be devoted to contributions which apply the principles of pharmacology to the use of these materials. Investigations which demonstrate no significant toxic effects will be published when of sufficient interest.

The Editors will welcome papers on acute, subacute, and chronic toxicity. Studies to determine the effective, tolerated, and lethal dose of chemicals may be published *per se* or as a part of an extensive investigation. Further, toxicologic data are acceptable which are concerned with the health and welfare of the community, including environmental and industrial toxicology.

The new periodical will be of particular interest to those working in the fields of toxicology, pharmacology, biochemistry, nutrition, veterinary medicine, and to those concerned in the manufacture and use of agricultural chemicals and medicinals, cosmetics, detergents, paints, plastics, lubricants, and fuels. Papers dealing with problems of air and water pollution, irradiation of foods and of food and feed additives will appeal to a wide audience.

Toxicology and Applied Pharmacology will accept for publication papers in the English language which are within the scope of the journal.

The publishers will supply fifty reprints free of charge to the senior author of each paper.

Manuscripts should be sent to the Managing Editor, DR. HARRY W. HAYS,
Toxicological Information Center, National Research Council,
2101 Constitution Avenue, Washington 25, D.C., U.S.A.

What are the Russians doing in my particular field?...

Is this information available in translation?

These pertinent questions, which consistently confront technical librarians today, have pointed up the serious lack of a *standard source of reference* for translations of Soviet scientific information, and have led to the inauguration of a unique monthly service . . . .

Soviet Science and Technology

THIS HANDY MONTHLY GUIDE, available on an annual subscription basis, is specifically designed to furnish Western scientists with *English translations of the contents* of current Soviet journals being translated, cover to cover, on a *continuing basis* by Consultants Bureau, other firms and learned societies.

THROUGH SPECIAL ARRANGEMENT with the editors of these Soviet publications, expedited copies of the contents are made available, in translation, within two months after their release in Russia. Thus, each subscriber is constantly aware of the latest information available for translation in his specific field of scientific endeavour.

The format of SST is one which permits the reader instant access to all pertinent information:

(a) *Estimated date of publication in English* (when information is available from publisher).

(b) *Name and Address of organization from which translation is available.*

(c) *Yearly subscription prices.*

(d) *Price of individual papers, or issues* (when sold separately).

(e) *A special section devoted exclusively to editorial material on the most up-to-date translating techniques.*

The worldwide acceptance of SST in its few short months of existence (*first published in May*, 1958) has proved the urgent need for just such a service. And with the constant addition of *new* Russian journals-in-translation, each subscriber is assured of continuous, comprehensive and accurate information on the availability of the latest advances in SOVIET SCIENCE AND TECHNOLOGY.

ANNUAL SUBSCRIPTION

(Includes 12 issues per year, which cover all calendar year issues of the original Russian journals)

1 copy	$25.00 per copy
10–100 copies	$18.00 per copy
100–500 copies	$15.00 per copy
500 copies and over ...	$11.50 per copy

(500 copies—includes, free of charge, your own special organizational cover.)

AVAILABLE FOR A LIMITED TIME

One volume containing the contents for all *1957* issues of these journals, with the same information as in the 1958 SST.............. $15.00

Write Consultants Bureau for free brochure on SST, and comprehensive catalogues of our current Russian translation-publishing programme.

Inquire re payment in Sterling.

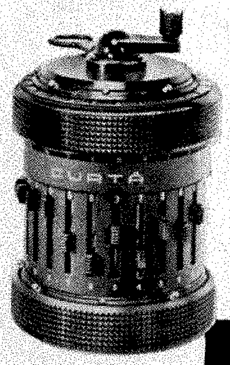
WHAT IS A BEAUTIFUL SHAPE?

Why is one shape considered attractive and another ugly? This question is one which mathematicians may soon be able to answer. Our photograph (copyright Science Museum London) shows a geometrical model of a three-dimensional surface, constructed by Mr. John Harvey, to illustrate mathematical principles. The equation for the surface is given below. The model is housed in the South Kensington Science Museum who kindly provided this picture.

$$(x+cy^2)^2+(z-y^{2/3})^2=a(k^2-y^2)^3$$



Shaping the course of industry is one of the mathematician's main pre-occupations to-day. Technological progress poses increasingly complex problems, demanding the highest mathematical skill and the very best computers. Which? . . . For major problems—electronic computers of course. For all other purposes the CURTA—the personal calculating machine that is fast becoming the constant companion of mathematicians, scientists, and technicians everywhere.

Only very occasionally does a new material appear that has a widespread potential throughout industry.

Here, though, is just such a product — a unique material that deserves your fullest understanding.

Refrasil

is the name given to a lightweight fibrous silica material, of very fine diameter, which is capable of withstanding continuously temperatures in the order of 1,000°C, or for short periods, even above. It has outstanding thermal insulating characteristics at elevated temperatures, as well as being an excellent high temperature electrical insulator. Like fused silica it has a high resistance to thermal shock and to chemical attack from acids.
It is available as batt, felted wool, cloth, tape, sleeving, bulk fibre, cord, and yarn.
There are many other things well worth your knowing about Refrasil; we have incorporated them all in a brochure which we would like to send you.

Pins and needles . . .

. . . bridges and bicycles,
we see steel in use all around us.
Steel that has to conform to strict
specifications, to ensure that its qualities
are suitable for its purpose.
Steel contains small quantities of such
elements as carbon, phosphorus and sulphur,
upon which its properties depend.
Because of this, it is essential that
the exact amount of these elements present
in the melt should be known just before
it is poured from the furnace.
That is why so many steelmakers rely
on the spectrograph for their analyses.

¶ The illustration shows a Hilger automatic spectrograph that determines the carbon, phosphorus, and sulphur in steel in a minute and a half. It operates in the far ultra-violet region, and uses fluorite optics housed in a vacuum chamber to prevent absorption of the rays.

BALDWIN DENSITOMETERS

These accurate electronic instruments, used with the Baldwin Photometer, measure or compare light intensity and density and colour of a wide variety of solids and liquids.
Baldwin Densitometers set high standards in accuracy and ease of operation and have innumerable uses in industry, research and photography—write for a copy of Brochure F-117 which gives complete information on the entire range.

REFLECTION DENSITOMETER

Density measurement and colour analysis of surfaces including black and white print density measurement; colour print comparison with the original; paint, plastic, ink and textile colour measurement; reflectance values and colour analysis of tiles, ceramics and very fine powders.

TRANSMISSION DENSITOMETER

Density measurement and colour analysis of all transparent and translucent materials including black and white film and paper, positive and negative colour film; opacity measurement of glass, plastics, resins; chromatogram analysis; colour filter transmission measurement and welding glass density measurement.

determination with a flame photometer, which showed a concentration of 840 m.equiv. sodium/l. in the secreted fluid.

Since the Galapagos lizard eats only seaweed which has a salt concentration similar to that of sea water, it is not only useful, but also a necessity, for it to have a mechanism for excretion of the salts in a high concentration.

In summary, we can conclude from observations described in this article that the combination of circumstantial (histological) and direct evidence (secretion of salt) indicates that an extrarenal mechanism for salt excretion is present probably in all four orders of marine reptiles, turtles, crocodiles, snakes and lizards. The secretion derives from head glands which resemble the salt glands of marine birds, both in structure and function. The kidney of birds and reptiles cannot produce a urine with high salt concentrations, and one can assume that the extrarenal mechanism for salt excretion is a necessity for successful adaptation to a marine habitat in all sauropsidians.

INFRA-RED SPECTRA OF A COALIFICATION SERIES FROM CELLULOSE AND LIGNIN TO ANTHRACITE

By Prof. C. R. KINNEY and E. I. DOUCETTE*

Department of Fuel Technology, Pennsylvania State University, University Park, Pa.

THE chemical processes involved in the transformation of the woody parts of plants into coal are not well understood. For the purpose of gaining insight into these processes, infra-red spectra of a series of coal-source materials from cellulose, lignin and wood through peat wood and a brown coal to typical bright coals of increasing rank have been compared. Significant changes in the spectra may be observed which reflect important chemical changes in the coalification series.

Characteristic spectra are reproduced in Fig. 1, and the sources of the samples are given in Table 1. The spectra were made using a 0·5 per cent concentration of finely ground sample in each case, dispersed in pressed potassium bromide plates. Consequently, the intensities of the absorptions should be only relative. Since the coals of low rank are harder to grind, the sloping background absorption in the region 2–6μ (Fig. 1) indicates that these samples were not ground finely enough to prevent some dispersion of the radiation at these wavelengths. Although this tends to decrease the relative intensity of the peaks in this region of these samples, the amount is not considered serious for making comparisons.

The strong absorption at about 8·5–10μ in the spectra of α-cellulose, holocellulose, lignin, fresh wood and peat wood (estimated to be 20 million years old) in Fig. 1 is unquestionably due to the stretching vibrations of carbon–oxygen bonds of various oxygen-containing groups which these materials are known to possess, particularly hydroxyl and ether linkages. On passing from peat to brown coal and to coals of higher rank there is a marked decrease in this absorption. Many of the coals contain considerable amounts of siliceous mineral matter which also absorbs at 9·7μ. In the coal spectra, the decrease in absorption between 8·5 and 10μ is accompanied by a corresponding decrease in the hydroxyl absorptions at 2·9μ and aliphatic carbon–hydrogen absorptions at 3·4–3·5μ. These changes accompany the disappearance of cellulose and lignin as such on passing from wood to coal, and must be due primarily to the loss of hydroxyl groups by the elimination of water molecules.

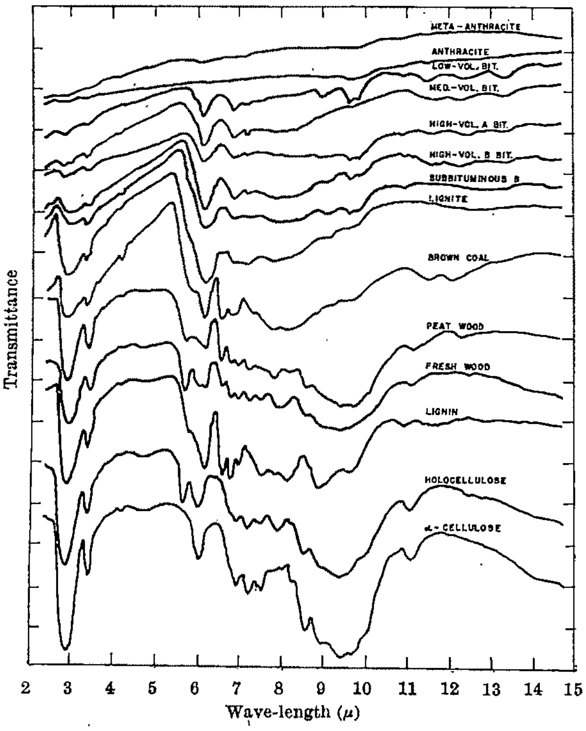

Fig. 1. Infra-red spectra of coal-forming substances and characteristic coals

Another absorption that is largely eliminated in the same early stages of coalification is the carbonyl band at 5·8μ in the spectra of holocellulose, wood and, to a lesser extent, in lignin and peat wood. In the spectra of the brown coal, this band is markedly reduced, and in the higher rank coals is practically eliminated. Adams and Pitts[1] find that bituminous coals protected from air oxidation have no band in this region. The 5·8μ band in the spectra of holocellulose and wood is believed to be due to acetyl groups which these materials contain and to the small amount of carbonyl present in the lignin structure. In peat it may be presumed that all of the acetyl groups would soon be removed by hydrolysis. This was confirmed by boiling a sample of wood with water for a number of hours and the 5·8μ absorption was reduced, similar to that in the peat spectrum. Also, the 6·0 and 7·9μ absorptions present in the fresh wood and holocellulose spectra were eliminated, with the result that the spectrum of the boiled wood was very similar to that of peat wood.

The broad absorption in the brown coal, centring at about 8μ, diminishes in lignite and coals of higher rank. This is accompanied by a corresponding loss in hydroxyl absorption at 2·9μ, and is no doubt due to the loss of phenolic hydroxyl groups as coalification progresses[2]. Since aliphatic carbon–hydrogen absorption at 3·4 to 3·5μ does not appear to decrease in intensity at the same time, it seems probable that the phenolic hydroxyl groups are not split out as water with aliphatic hydrogen atoms. Aromatic ether linkages absorb strongly at about 8μ and a part of the decrease in absorption in this region, as brown coal undergoes further coalification, may be due to the elimination of ether linkages.

The development of the strong band at 6·2μ in coal spectra (Fig. 1) is of particular interest. This is the region of double-bond stretching vibrations, particularly C=C bonds, and in coal spectra this absorption has been assigned to aromatic structures[3-5]. Other authors[6-8] have proposed that at least a part of this absorption is due to groups containing oxygen, particularly hydrogen-bonded quinones. The spectra of cellulose, holocellulose, and wood all show an absorption at 6·0μ, which may be due to hydrogen-bonded carbonyl groups, but this band disappears at the peat stage with no corresponding increase in the 6·2μ absorption. Consequently, it appears that the cellulosic constituents of wood are not the source of this absorption.

Lignin, on the other hand, has a strong 6·2μ band, which is observed in the spectra of wood, peat and the various coals to the semi-anthracite rank with but little diminution of intensity from wood to semi-anthracite. In the spectrum of lignin, the 6·2μ band is undoubtedly due to the benzene rings which this material contains. The 6·2μ band in lignin is accompanied by a second band at 6·6μ, as is frequently observed with benzene derivatives. These two bands of nearly equal intensity may be observed in the spectra of wood, peat and the brown coal, but in the lignite spectrum the absorption at 6·6μ is greatly reduced and is completely absent in the spectra of higher rank coals. This loss in absorption at 6·6μ on passing from low-rank to high-rank lignites was observed with three additional samples of the former and four of the latter, suggesting that the 6·6μ band disappears in the early stages of coalification. Brown[6] has also pointed out that the 6·6μ band is generally weak or absent in spectra of known condensed aromatic hydrocarbons containing more than three rings. This band is also absent from spectra of coal tar pitches[5], which are composed of mainly large condensed aromatic structures. Therefore, it seems probable that the cause of the disappearance of the 6·6μ band is the condensation of benzenoid derivatives characteristic of lignin into polynuclear fused-ring aromatic structures characteristic of coals[9].

The bands at 6·9 and 7·2μ in the coal spectra, together with bands at 3·4–3·5μ, have been assigned to aliphatic carbon–hydrogen groups[3,4,6]. The persistence of these bands throughout the bituminous range of coals shows that this structural element is one of the last to disappear. The absence of these bands in the spectra of anthracites may be due more to their obliteration by a general electronic type of absorption[3] rather than to a complete elimination of these structures.

A comparison of the spectra of the coalification series from cellulose and lignin to anthracite gives an insight into the chemical changes that occur during coalification. Of particular interest are the loss of oxygen and the development of aromatic absorption characteristic of condensed polynuclear aromatic structures.

Undergraduate Academic Record of Fellows of the Royal Society

At the present time the main criterion for the award of grants for postgraduate research seems to be the candidates' undergraduate academic record. As a preliminary attempt to measure the validity of this practice, we have examined the published class of degree gained by current Fellows of the Royal Society who received their first degree from Oxford or Cambridge. Our results are given in Tables 1 and 2. Oxford and Cambridge are listed separately, and in each case the results of those who graduated during the period 1920–39 are given as well as the results for the group as a whole. For the Oxford group the result given is always that gained in the Final Honours School; for the Cambridge group the results given in Table 1 are of the last Tripos taken irrespective of whether it was Part 1 or Part 2, while Table 2 gives the results of an earlier Tripos if one was taken. The figures in brackets represent the actual totals on which the percentages are based.

Table 1. Results in Final Honours School (Oxford), or Last Tripos (Cambridge)

Cambridge					Oxford				
Class	1920–1939	Per cent	1886–present	Per cent	Class	1920–1939	Per cent	1907–present	Per cent
1	(70)	76·9	(139)	78·5	1	(30)	96·8	(36)	97·3
2	(19)	20·9	(34)	19·2	2	(1)	3·2	(1)	2·7
3	(2)	2·2	(4)	2·3	3	—	—	—	—

Table 2. Cambridge Tripos Results for Part 1 and Part 2

Class		Cambridge			
Part 1	Part 2	1920–1939	Per cent	1886–present	Per cent
1	1	(50)	54·9	(95)	53·7
2 or 3	1	(8)	8·8	(14)	7·9
1	2 or 3	(10)	11·0	(20)	11·3
2 or 3	2 or 3	(7)	7·7	(9)	5·1
1		(12)	13·2	(30)	16·9
2 or 3		(4)	4·4	(9)	5·1

If we assume that Fellows of the Royal Society have demonstrated outstanding research ability and that examination standards at Oxford and Cambridge have remained relatively constant (at least during the period 1920–39), and if academic records are a good predictive criterion of research ability, we should expect to find a negligible proportion within our criterion group who gained anything other than first class degrees as undergraduates. Therefore our first finding (Table 1) that approximately 1 in 4 of the group who graduated from Cambridge during the period 1920–39 gained a second or third in their final examination, and that (Table 2) approximately 1 in 3 gained either a second or third at some time during their undergraduate careers seems surprising. Our other principal finding, namely, that the Oxford group appear to have better undergraduate records than the Cambridge group, seems open to at least two interpretations: (1) that the Oxford examination is actually a more valid index of potential research ability than is the Cambridge one; and (2) that the standards of the Oxford examinations are relatively lower than they are at Cambridge. A third possible interpretation, that the sample is inadequate to make the difference significant, is unlikely at the 0·5 per cent level of confidence using the χ^2.

Although the present data do not enable us to state the general relation between undergraduate academic achievement and research ability, we believe that considerable doubt has been cast on the use of degree class alone as a criterion for the selection of research students. In order that a more precise assessment may be made, we hope to carry out the following further investigations: (1) compare the proportion of degree classes gained by Fellows of the Royal Society with the proportion gained by the population of research students at Oxford and Cambridge during the relevant period; (2) extend the list of Fellows to include those who graduated from universities other than Oxford and Cambridge; and (3) examine other criterion groups, such, for example, as D.Sc.'s. The encouragement of Profs. F. G. Young and O. L. Zangwill throughout this inquiry is gratefully acknowledged.

Effect of Air Drag on the Orbit of an Earth Satellite

It has been shown[1] that the first-order effect of the oblateness of the Earth can be simply incorporated in the standard analysis of the effect of air drag on a satellite orbit. However, King-Hele and Leslie[2] ignore this correction in a comparison of theory and observation on the orbit of *Sputnik* 2 (1957β) in favour of terms of higher order in the eccentricity.

There appear to be two distinct problems in the fitting of the observational data, as typified by the

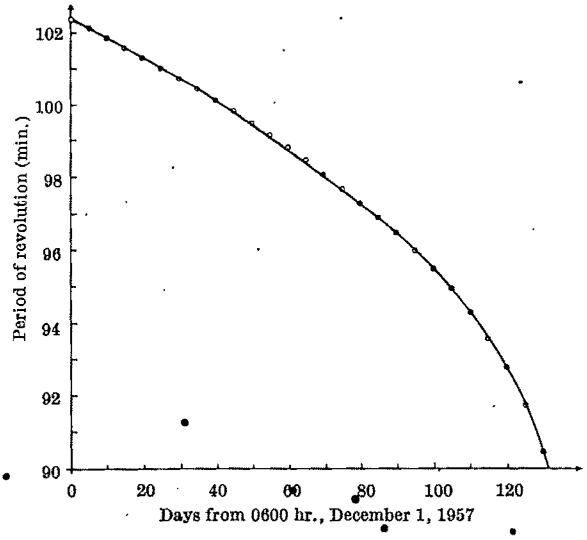

Fig. 1. Period of *Sputnik* 2 —, observed; ○, calculated

prediction of the orbital period over a range of the order of months on one hand and by the day-to-day variation in the rate of increase of the periodic time on the other. This second problem obviously requires a consideration of effects which are ignored in the customary analysis, of which the tidal influences of the Moon may well be one. However, the variations of this second type appear to be grouped about a mean behaviour consistent with the simple analysis. Thus Fig. 1 shows a comparison between the observed orbital period and that calculated on the relation given by me[1] over the period December 1–April 10. Here only first-order terms in e_0 are retained, but a correction for oblateness is included. The value of t_n was taken as 134·4 days and the scale-height was estimated at 33·5 nautical miles. The fit is decidedly better than that of King-Hele and Leslie, the only noticeable departure of the calculated values occurring in January when observations indicated a change in the effective drag cross-section. It should be noted that this agreement has not been obtained by an arbitrary assignment of parameters, since t_n is critically determined by the time of final fall and the only assignable parameter is the scale-height H. Undoubtedly the assumption of constant scale-height is violated in practice; but unless the agreement is purely fortuitous, it would appear that it varies little between 112 nautical miles and 95 nautical miles above the surface of the Earth. There is, however, some indication in the orbital data of a slight decrease in the value at lower levels.

It would seem that for prediction 'in the large' an analysis correct to the first order in e_0 but including a correction for the oblateness of the Earth is entirely adequate. This is further borne out by the fact that the failure of the asymptotic expansions of the Bessel functions at small values of the eccentricity is illusory, since the instability of the 'circular' form implies a non-zero minimum value of e. The second problem, that of accounting for the variations in the very sensitive rate of increase of periodic time, quite obviously requires considerably wider physical assumptions and is consequently beyond the scope of the present analysis.

D. G. PARKYN

Department of Mathematics,
University of Natal,
Pietermaritzburg.

[1] Parkyn, D. G., *Nature*, 181, 1156 (1958).

[2] King-Hele, D. G., and Leslie, D. C. M., *Nature*, 181, 1761 (1958).

IN the theoretical formula for the variation of the period of revolution with time, there are three roughly equal small terms, with coefficients e^2, H/a_0 and ε (the Earth's ellipticity). Mr. Parkyn obtains a good fit by ignoring the first two of these and retaining the third. It is not altogether satisfactory, however, when two terms which should apparently be included have to be omitted. Rather it suggests that some of the assumptions in the theory need to be improved; that was why we were reluctant to assign a value of H in our article, and we should be even more reluctant to guess its variation with height.

The Fundamental Molecular Event in Muscular Contraction

ASTBURY[1 2] suggested that the fundamental event in the contraction of muscle might involve a characteristic of the keratin–myosin–epidermin–fibrinogen group of fibrous proteins to which myosin belongs, namely, the folding or collapsing of polypeptide chains from the α-configuration into the supercontracted state. While it has been shown that isolated myosin and actomyosin supercontracts after reasonably mild chemical or physical treatment[2,3], no X-ray evidence has been forthcoming so far to show that the shrinkage of actomyosin gels after treatment with adenosine triphosphate is accompanied by a corresponding configurational change[4]. Moreover, there is the difficulty of reconciling this approach with recent concepts of a two-phase actin–myosin system shortening by close-range[5] or long-range[6] interaction of filaments coiling or sliding over one another in a regular stepwise fashion.

The demonstration by Astbury, Beighton and Weibull[7], in diffraction diagrams of bacterial flagella, of X-ray features characteristic of the supercontracted state (the 'cross-β' configuration[8]) side by side with an α-pattern having analogies with that of muscle suggests that the simplest molecular expression, of flagellar motility in any event, may be a rhythmic interchange between the α-state and a shorter supercontracted form. Recently, the discovery by Rudall[9] of a transversely folded protein in the egg-stalk of the lace-wing fly *Chrysopa* has much emphasized the possibility that there may commonly exist in Nature (as opposed to mechanical or chemical artefacts) a well-defined protein state in which the polypeptide chains lie in long regular folds[10].

We now report that the synæresis of actomyosin on addition of adenosine triphosphate is accompanied by X-ray indications of a transformation of a proportion of the protein into the supercontracted state.

The actomyosin used was extracted from the finely crushed dorsal muscle of fish by buffered alkaline potassium chloride and precipitated by lowering the ionic strength. After washing three times, with interspersed centrifugation, the actomyosin formed transparent thixotropic gels, still intensely reactive to adenosine triphosphate solutions[11] and capable of being dried on water-repellent glass blocks to form thin transparent films. The unsynæresed films could easily be stretched in moist air to give well-oriented α-diagrams characterized by the familiar meridional reflexion at about 5·1 A. After synæresis with adenosine triphosphate, the resultant opaque brittle films were difficult to handle, and the diffraction patterns of such unpromising material appeared to show only a vague sharpening on the meridian. By washing out the reactants immediately after addition of adenosine triphosphate, however, the partly contracted gels retained a certain capacity to stretch after drying, and such specimens could be sufficiently oriented to illustrate changes in the diffraction pattern.

Fig. 1 shows the diffraction pattern of a film prepared as just described of actomyosin from the dorsal muscle of the ruffe, *Acerina vulgaris*. The 'cross-β' configuration shows up as a faint preferred orientation at 4·65 A. on the meridian. The conditions for the appearance of an X-ray pattern indicating supercontraction in actomyosin appear to be very critical;

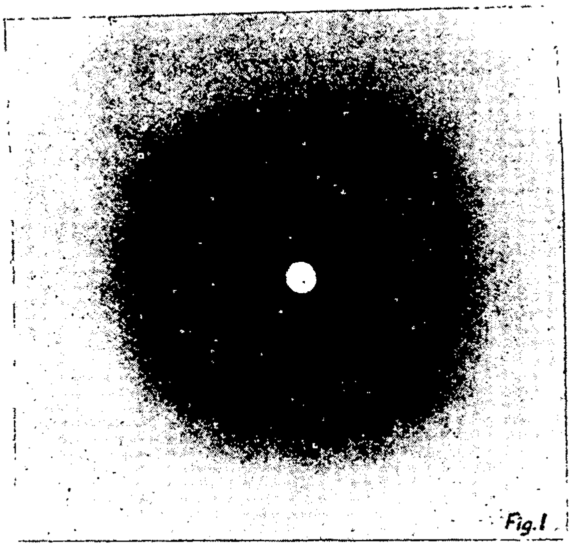

Fig. 1. Actomyosin from *Acerina vulgaris* partly contracted with adenosine triphosphate. Thin films stretched about 50 per cent in moist air and photographed with the X-ray beam parallel to the film

this is understandable if the circumstances of protein chain-folding are such as to obstruct orientation by stretching.

A detailed account of this work will appear in due course. I am indebted to Prof. W. T. Astbury for his encouragement, to Dr. K. M. Rudall for advice, and to Mr. A. Millard for reproducing the X-ray diffraction photograph shown in Fig. 1.

Calibration of a Calorimeter: a Minor Peaceful Use for Plutonium

CALORIMETERS are often calibrated by generating a known electric current within them and observing the deflexion of the measuring instrument when the system is in a steady state. This method may suffer from the disadvantage that heat is lost along the leads through which the calibrating current is introduced. The loss of heat can be reduced by passing the leads through a block of metal maintained at the experimental temperature, though the design of the calorimeter and its water-bath may make this procedure difficult. One can also calculate the loss of heat along the heater leads, but it is not desirable to rely exclusively on estimates that cannot be verified by experiments. One alternative is to calibrate the heater against some thermochemically convenient reaction, for example, the latent heat of vaporization of a liquid[1], or the neutralization of a strong acid by a strong base[2]. These methods have their own disadvantages, and it was therefore decided to use a different method of calibration, either of the calorimeter itself or of the heater used to calibrate it.

This method, which involves putting into the calorimeter a radioactive substance in equilibrium with its disintegration products, in a radiation-absorbing container, was first used by Boivinet and Calvet in 1954[3]. They inserted into their calorimeter a platinum and gold needle containing 10 mgm. radium in equilibrium with its disintegration products, which produced about 95 mcal./hr. The radium needle was electrically calibrated in an adiabatic calorimeter in which the heat conduction along the heater leads was said to be negligible[4].

Radium has certain disadvantages for this purpose: first, radium-226 and its decay products are strong γ-emitters, which is not conducive to ease of handling in a very small calorimeter. Secondly, unless the percentage of radium-228 in the sample of radium-226 is known, theoretical estimates of the energy output of the sample cannot be precise. Plutonium-239 does not suffer from these drawbacks and has the additional advantage that its only decay product, uranium-235, is very stable, having a half-life of 7·07 × 10^8 years. Plutonium-239 was obtained by irradiating uranium-238 with slow neutrons in BEPO at the Atomic Energy Research Establishment, Harwell. The following reactions occur:

$$\begin{tikzcd}[column sep=small] {}^{238}\mathrm{U}(n,\gamma){}^{239}\mathrm{U} \arrow[r, "\beta"] & {}^{239}\mathrm{Np} \arrow[r, "\beta"] & {}^{239}\mathrm{Pu} \arrow[d, "{(n,\, 2n)}"] & (n,\gamma){}^{240}\mathrm{Pu}(n,\gamma){}^{241}\mathrm{Pu} \\ & & {}^{238}\mathrm{Pu} & \end{tikzcd}$$

The amounts of plutonium-238 and americium-241, plutonium-240 and plutonium-241 were, respectively, 0·3 per cent (by activity), 0·977 per cent and about 0·016 per cent. According to Asaro and Perlman[5], the total disintegration energy of plutonium-239 is 5·235 MeV./nucleus and the same value can be deduced from the earlier data of Gol'din, Tret'yakov and Novikova[6]. 99·6 per cent of the γ-rays emitted by plutonium-239 can be shown to be absorbed by the platinum/iridium needles in which the plutonium (as PuO_2) is contained. As 1 MeV. = 3·829 × 10^{-11} mcal. and the half-lives of plutonium-239, -240 and -238 are 24,360, 6,580 and 89·6 years[5], the heat output of the plutonium oxide can be shown to be 1·4891 mcal./mgm./hr.

The two needles containing the plutonium oxide were standard radium needles, external length 30 mm., external diameter 1·65 mm. and wall thickness 0·5 mm. They were believed to contain 41·58 and 49·66 mgm. PuO_2, though some of this may have been lost during sealing the needles. Using the value 1·4891 mcal./mgm./hr., a theoretical estimate of the heat production of the needles can be made (Table 1). The actual energy output of the needles (Table 1) was measured by Dr. W. B. Mann, of the National Bureau of Standards, Washington, D.C., using a Callendar radiation balance[7]. The radiation balance is, in fact, the microcalorimeter in which the quantity of heat to be measured is balanced against the cooling from Peltier couples, in such a way that no corrections are needed for the Joule heating in the Peltier couples

Table 1. Energy Output of PuO_2 in mcal./hr.

Needle	Calculated	Measured (Mann)
1 2	61·92 73·95	62·26 ± 0·35 74·48 ± 0·35
1 ÷ 2 (measured)	0·8326 ± 0·0043 (Mann)	0·8292 ± 0·0089 (Rothschild)

and leads. This method of measuring heat production does not have the disadvantages mentioned earlier.

Using a modified Clarke–Rothschild calorimeter[2], volume 2·4 ml., for which the plutonium oxide needles were made, I obtained a value for the ratio needle 1/needle 2 of 0·829, as compared with Dr. Mann's value of 0·833. The difference, of about 0·6 per cent, between the calculated and observed energy outputs may be due to an error in the value taken for the half-life of plutonium-239, or to the sample not being pure PuO_2, or to the amount of americium-241 present.

I am greatly indebted to the U.S. National Bureau of Standards and, in particular, to Dr. W. B. Mann, for measuring the heat output of the plutonium needles; and to Dr. G. B. Cook, of the Isotope Division, Atomic Energy Research Establishment, Harwell, for much assistance and advice. This work is supported by the Medical Research Council.

Visualization of Mode Conversion of an Ultrasonic Beam in Fused Quartz

In investigating methods of bonding transducers to fused quartz for use in delay lines, it is very useful to be able to see how the ultrasonic beam travels through the quartz.

To visualize the paths of such beams, we have employed the optical system described by Sven Johnson[1], which makes use of the following two principles: (1) a diffraction grating is produced in the quartz by the periodic variations of density in the path of the ultrasonic beam[2]; if the quartz be viewed in a schlieren system, only the vibrating portions of the quartz should be visible; (2) in the regions of high ultrasonic strain the quartz becomes birefringent; thus, placing the quartz between crossed 'Polaroids' will cut out the effect of scattered light without blocking the ultrasonic field from view.

Fig. 1 is a photograph, taken by this method, which gives a vivid illustration of the phenomenon of mode conversion on reflexion.

On reflexion of a compressional wave at a plane interface between a solid and air, both compressional and shear waves will be reflected. Arenberg[3] has calculated that, in fused quartz at an angle of incidence of 44·8°, there will be complete mode conversion from a compressional wave to a shear wave reflected at an angle of 27·2°:

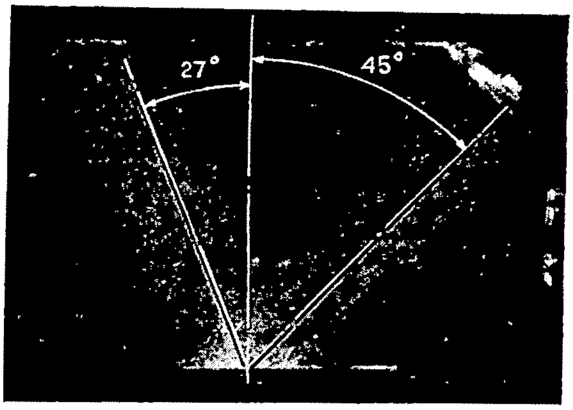

Fig. 1

$$\left(\frac{\text{sine angle incidence}}{\text{sine angle reflexion}} = \text{ratio of velocities}\right)$$

An X-cut quartz crystal, affixed to the Heraeus quartz blank by an indium bond, is excited at its resonant frequency of 8·5 Mc./s., thus injecting the compressional wave into the quartz (which has been machined to give the required angle of incidence). Fig. 1 shows the beam reflected at an angle of 27° and no sign of any reflexion at 44·8°. Some standing waves in the ultrasonic field are visible. Multiple reflexions have been reduced by absorbing material on the faces of the blank.

Acknowledgments are made to Mr. K. P. Osmond for the preparation of the bond and to Mr. A. Allen, chief development engineer of Cossor Radar and Electronics, Ltd., for permission to publish this communication.

Scattering of Microwave Radiation by a Plasma Column

The purpose of this communication is to describe experiments performed to determine the angular distribution of the electromagnetic radiation scattered by the positive column of a mercury discharge under the resonant conditions which have been previously investigated[1,2]. The experiments reported here prove the multiple order of the three largest resonances shown in Fig. 1 to be dipole.

The conditions for production of the series of resonances in the scattered radiation are that (1) the E vector of the incident radiation be perpendicular to the axis of the plasma column, (2) the diameter of the column be small compared to the wave-length of the radiation, and (3) the frequency of the radiation be in the vicinity of the so-called plasma frequency.

The following experimental arrangements were made in order to satisfy the foregoing conditions.

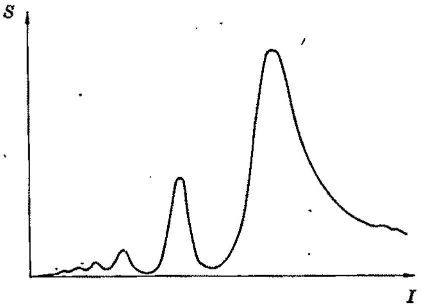

Fig. 1. Intensity of scattered radiation (S) as a function of positive column current (I). (Adapted from A. Dattner, ref. 2)

Microwave radiation of 10-cm. wave-length was coupled to a guide which was terminated by a tapered horn. The horn was arranged so that the E vector of the emergent radiation would be perpendicular to the axis of the plasma column. The plasma was contained in a glass tube of 8 mm. inside diameter and 47 cm. length. The glass tube was located directly in front of the horn at a distance of 30 cm. The discharge 'bulb', which was immersed in an oil bath, contained a mercury pool cathode and a hold anode. The bulb was connected to the lower end of the glass tube.

In order to reduce the amount of radiation scattered by the room walls and other objects, the area around the horn and scattering column was enclosed on the sides by panels of microwave absorbing material. The H component of the field of the scattered radiation was measured as a function of scattering angle using a 7-mm. diameter circular loop placed perpendicular to and 65 cm. distant from the axis of the plasma column. To minimize the amount of direct radiation from the horn to the pickup loop an additional absorbing panel was located between the horn and loop. The position of this panel was adjusted to produce a null output from the detection system at each loop position when the positive column was not ignited. Care was taken to ensure that adjustments of the panel did not measurably affect the intensity of the radiation incident on the column nor shield the loop from the column.

The positive column current was modulated by use of a 50-c./s. sine wave superimposed on a direct current. The amplitudes of the direct and 50-c./s. currents were adjusted so that electron densities corresponding to the five most pronounced resonances were swept through on each cycle.

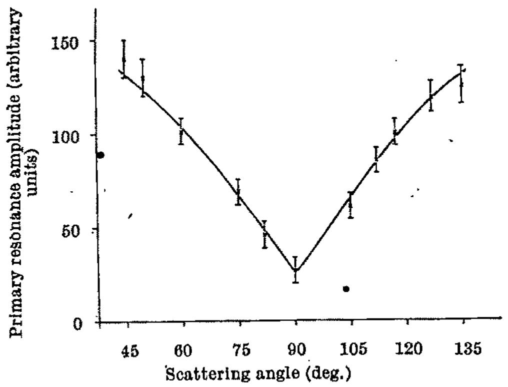

Fig. 2. Amplitude of the primary resonance as a function of the scattering angle

After amplification and detection, the loop output was displayed on the vertical axis of an oscilloscope the horizontal deflexion of which was made proportional to the positive column current. Thus the oscilloscope displayed a plot of the scattered radiation field as a function of the column current at a particular scattering angle. Using the foregoing arrangements, it was possible to determine the amplitude of the three largest resonances for scattering angles, θ, between 45° and 135° with respect to the incident direction.

Fig. 2 shows a plot of the amplitude of the largest or primary resonance as a function of scattering angle. Also shown in Fig. 2 is the curve $25 \sin \theta + 165 \cos \theta$, which is seen to provide a reasonable fit. The addition of the small $\sin \theta$ term to the anticipated $\cos \theta$ dependence of a dipole H field is due to the presence of some electrical pickup by the loop and its cable. There is no evidence of higher multipoles. Thus the primary resonance is dipole. The sizes of the plus–minus bars attached to each point were based on the accuracy with which the null adjustment of the movable absorbing panel could be made and on the noise level of the system.

Table 1. THE RATIOS OF THE SECONDARY (2) AND TERTIARY (3) TO PRIMARY (1) RESONANT AMPLITUDES AS A FUNCTION OF SCATTERING ANGLE θ

θ	(2)/(1)	(3)/(1)
45	0·27	0·12
54	0·25	0·13
60	0·23	0·10
75	0·28	0·14
82	0·24	0·09
90	0·23	0·08
97	0·27	0·07
105	0·23	0·10
112	0·27	0·15
120	0·23	0·08
127	0·29	0·12
Average ratio	0·25	0·11
RMS deviation	0·02	0·02

Table 1 gives the ratios of the secondary and tertiary resonant amplitudes to the primary resonant amplitudes as a function of scattering angle. Neither of these ratios have angle dependent trends of sufficient amplitude to indicate any difference in multipolarity among the three resonances. Thus, since the primary resonance is dipole, all three must be dipole. It is perhaps safe to suppose that the other resonances behave similarly, but the noise level of the system prohibited the accurate measurement of the higher modes.

Calculations made by Makinson and Slade[3] appear to predict multiple dipole resonances while other results[4,5] have indicated a single dipole resonance. The present experiment supports the result of Makinson and Slade.

It is a pleasure to acknowledge the extensive assistance given this work by Mr. Adam Dattner and to thank Prof. H. Alfvén for his hospitality, encouragement and the use of laboratory facilities.

Transformation of the α- and β-Forms of Calcium Sulphate Hemihydrate to Insoluble Anhydrite

ALTHOUGH there is no difference between the X-ray diffraction patterns of α- and β-calcium sulphate hemihydrate[1], differences have been reported for density, specific heat and the heat of formation[2]. I have shown that the dehydration of each form to soluble anhydrite proceeds at about the same rate, but that the rate of transformation of soluble to insoluble anhydrite is much greater for the α-form. This is of importance in the examination of gypsum plasters, which may contain one or both of these forms according to the method of manufacture. The difference between the α- and β-forms is demonstrated here by simultaneous differential thermal and thermogravimetric analyses[3], and by determining the rate of the phase transformation at a static temperature.

Samples of α-hemihydrate were prepared by heating a pure precipitated gypsum in concentrated nitric acid[1], in a saturated steam atmosphere[2], and in a concentrated solution of magnesium sulphate[4]. Samples of β-hemihydrate were prepared by calcining the same gypsum in open dishes in an air oven at 150°, 200° and 240° C. The differential thermal curve for α-hemihydrate (Fig. 1, curve *a*) indicates the rapid formation of insoluble anhydrite by a sharp exothermic peak at 255° C. The form of the curve was the same for a large number of samples prepared by the methods outlined above. Although in some instances a reduction in the size of the exothermic peak was noted, the claim by Budnikov and Kosyreva[5], that the differential thermal curve for α-hemihydrate shows no exothermic effect, is not in agreement with my results. The simultaneous thermogravimetric curve showed that the water content of the sample was about 0·1 per cent when the exothermic reaction commenced, and X-ray examination of the sample heated to 290° C. (the end of the exotherm) showed that it contained about 60 per cent insoluble anhydrite. Further conversion of the α-soluble anhydrite to insoluble anhydrite took place slowly between 290° and 550° C., with a loss of about 0·05 per cent of water. The β-hemihydrate behaves differently. The differential thermal curve (Fig. 1, curve *b*) indicates a gradual transformation to insoluble anhydrite commencing at about 300° C. The simultaneous thermogravimetric curve indicates that at 300° C. (the beginning of the exotherm) the water content was reduced to about 0·2 per cent, and X-ray examination of the sample heated to 500° C. (the end of the exotherm) showed that it was almost pure insoluble anhydrite. By comparison, it should be noted that in the decomposition of the α-hemihydrate a small amount of soluble anhydrite still remained at 500° C.

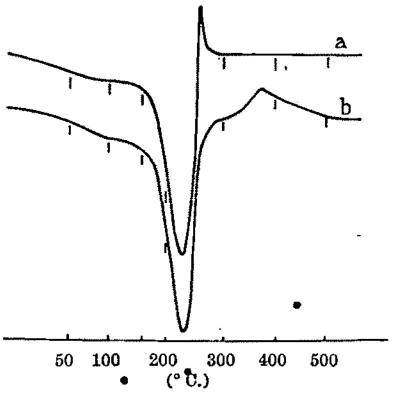

Fig. 1. Differential thermal analysis curves for calcium sulphate hemihydrate. *a*, α-form ; *b*, β-form

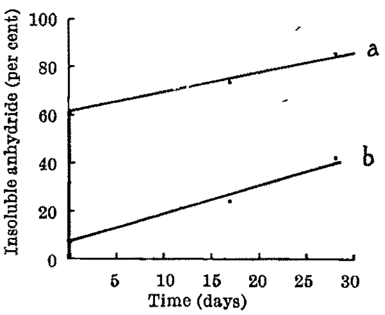

Fig. 2. Rate of formation of insoluble anhydrite from calcium sulphate hemihydrate at 200° C. *a*, α-form ; *b*, β-form

In a mixture containing α- and β-hemihydrate the exothermic peak of the α-form is often not visible on the differential thermal curve because it is masked by the endotherm of the β-form, which is not complete until about 300° C. ; but the form of the curve is still different and the area of the exothermic peak due to the β-form is significant. It is reduced to about half its normal size in a mixture of equal parts of α- and β-hemihydrates, and can therefore give an indication of the proportion of each form present. The area of each exothermic peak of β-hemihydrate was not appreciably different for samples prepared by heating at 150° C. for 4 hr., at 200° C. for 1 hr., and at 240° C. for 45 min.

The phenomena observed under dynamic heating conditions were also observed at a static temperature of 200° C. Fig. 2 shows that initially the rate of transformation of the α-form to insoluble anhydrite is about eight times greater than that for the β-form, but thereafter the rate decreases to about half that of the β-form.

I wish to thank Dr. W. F. Cole for taking the X-ray photographs.

Estimation of Strontium in Biological Materials by means of a Flame Spectrophotometer

PREVIOUS attempts to determine the strontium content of biological materials by spectrochemical methods have not been entirely satisfactory, and in at least one investigation[1] the method was abandoned in favour of neutron activation analysis. With recent improvements in the performance of flame spectrophotometers which have been described by various authors[2] methods have been evolved for the assay of calcium and magnesium which claim a high accuracy.

Need has arisen in this laboratory for a rapid and reliable means of estimating strontium in biological material as a result of the continued study of the turn-over of strontium in man and experimental animals. A method, based on neutron activation analysis, has already been described[3]. Although this is regarded as both sensitive and accurate, the procedure is laborious and, in an extended metabolic study, these radiochemical estimations are time-consuming and involve carrying out the estimation in the vicinity of a nuclear pile. I have devised a rapid and accurate method for the estimation of strontium in which an *S.P.* 900 'Unicam' flame spectrophotometer is used.

(*a*) *Chemical procedure*. Since strontium is only a trace element in biological material, ranging in human plasma from about 0·03 p.p.m. to about 600 p.p.m. in human fæcal ash, some chemical treatment of the material is necessary. (The specimens should contain at least 5 μgm. of strontium.) Urine or plasma was precipitated with excess ammonium oxalate at about neutral *p*H. All solid materials such as bone, tissue or fæces were dry-ashed overnight at about 650° C. The subsequent treatment involved the removal from the ashed material of much of the alkali and phosphate, which otherwise interferes with the spectrochemical estimation of the strontium. All solids were therefore dissolved in 2 *N* hydrochloric acid. (A suitable aliquot was withdrawn at this stage for calcium estimation, which was assayed either by a modified ethylenediaminetetraacetic acid method which is shortly to be described or by means of the flame spectrophotometer.) Strontium and calcium were reprecipitated as oxalates and, after centrifuging and discarding the supernatant, the residues were dissolved in concentrated nitric acid. The concentration of nitric acid was then increased to 85–90 per cent by the addition of fuming acid. After standing in iced water for 10 min., these specimens were centrifuged and the supernatant again discarded. The insoluble nitrates (mainly of calcium and strontium) were then dissolved in water and made up to a concentration of between 1 and 5 p.p.m. in strontium in a suitable volumetric flask (25 or 50 ml., say).

(*b*) *Spectrophotometric assay*. A known aliquot, say 0·1 ml., of a standard strontium solution containing 200 p.p.m. of 'Specpure' strontium was placed in a 10-ml. volumetric flask and this was then filled to the mark with the nitrate extract already prepared. An internal standard is thus obtained and the two solutions were assayed directly on the flame spectrophotometer using the strontium line at 460·7μ, a slit-width of about 0·05 mm. and a gain setting of about 5. Deflexions were recorded on a galvanometer.

In order to eliminate any interference from calcium or other ions on the strontium readings, the galvanometer deflexion was also observed at about 5μ on either side of the strontium wave-length. These settings gave zero deflexions on a pure strontium solution but usually small deflexions were observed in the case of tissue or excreta extracts. The mean deflexion, φ, which was regarded as a white radiation background, was subtracted from the two deflexions θ_1 and θ_2, θ_1 corresponding to the unknown solution of strontium content X and θ_2 to the second solution. Then, if C denotes the known addition of strontium made :

$$\frac{X + C}{X} = \frac{\theta_2 - \varphi}{\theta_1 - \varphi} \text{ or } X = \frac{(\theta_1 - \varphi)C}{\theta_2 - \theta_1}$$

provided the galvanometer readings so corrected are proportional to the concentration of strontium. This condition was verified using a variety of concentrations over the range 0–10 p.p.m. Table 1 shows the comparison between the strontium content for various samples as determined on the spectrophotometer with that determined by neutron activation.

Table 1

Specimen	Strontium content Flame photometer	 Neutron activation
Fæcal ash 1	7·28 mgm./day	7·23 mgm./day
Fæcal ash 2	5·28 ,, ,,	5·45 ,, ,,
Fæcal ash 3	5·72 ,, ,,	5·45 ,, ,,
Urine oxalate 1	0·137 ,, ,,	0·153 ,, ,,
Urine oxalate 2	0·187 ,, ,,	0·188 ,, ,,
Cow's milk ash 1	36 p.p.m.	35 p.p.m.
Cow's milk ash 2	49 ,,	37 ,,
Diet ash	74 ,,	80 ,,

This comparison is illustrative of the general agreement which we have obtained between the two methods. It is concluded that the error as deduced from such comparisons as shown in Table 1 and from the reproducibility of individual determinations is between 2 and 3 per cent at strontium concentrations of about 2 p.p.m.

Observation of Transient Intermediates in Redox Processes by Variable Voltage Oscillo-polarography and Cyclic Voltammetry

THE dropping mercury electrode can be used for oscillo-polarography[1] but the oscillo-polarograms obtained during the investigation of organic compounds are often difficult to interpret.

Recent work in this laboratory has led to the development of a 'hanging' mercury drop electrode which has proved of value in the analysis of both inorganic and organic solutions[2,3]. This electrode yields oscillo-polarograms in which a clear and stable image is produced and any desired potential between 0 and − 2 V. can be applied. This feature, in combination with the possibility of using current of any frequency, makes interpretation of the results much easier and also permits the observation of the existence in solution of short-lived intermediates which do not appear in ordinary polarograms.

Some results which confirm this are shown in Fig. 1, the solution employed being a 2×10^{-4} *M* *p*-nitroaniline in 0·1 *N* potassium hydroxide.

The curves shown on the right-hand side of the diagram are (1) the polarograms obtained by use of the dropping electrode, and (2) the hanging drop cyclic voltammetric curves. In the latter it is seen that the first reduction cycle shows only the peak corresponding to the polarographic wave (1).

This corresponds to the following reduction :

$$NH_2C_6H_4NO_2 + 6e + 6H^+ \rightarrow NH_2C_6H_4NH_2 + 2H_2O;$$

in the first, and subsequent oxidation cycles, however, a minimum at − 0·06 V. is seen and this corresponds to the oxidation :

$$NH_2C_6H_4NH_2 - 2e - 2H^+ \rightleftharpoons NHC_6H_4NH$$

This reaction is reversible and so, in the subsequent reduction cycles, a peak is observed at about −0·10 V. The above mechanism is supported by our finding that the curves obtained for *p*-phenylenediamine are identical with those discussed here.

The corresponding oscillo-polarograms are shown on the left-hand side of the diagram. The span of the widest curves (7) and (8) corresponds to − 1·8 V., the current being of 50 cycles/sec. Trace (7) corresponds to the cyclic trace (2) on the right-hand side of the diagram. Five 'cuts-in' are seen. Those at about − 0·1 V. correspond to the *p*-phenylenediamine/*p*-di-iminoquinone system while the six electron reduction of *p*-nitroaniline, being irreversible, corresponds to the single cut-in at about − 0·80 V. The pair of cuts-in at − 0·50 V., however, have no parallel in (2) and so must correspond to a new redox system of such low stability as to be detectable only by use of high frequency current.

This system may correspond to the reaction

$$NH_2C_6H_4NO - 2e + 2H^+ \rightleftharpoons NH_2C_6H_4NHOH$$

the nitrosoaniline being derived, possibly, from the incomplete reduction of nitroaniline under oscillo-polarographic conditions. The evidence for this supposition is not very strong and further attempts at identification are in progress. Nevertheless, the cuts-in undoubtedly correspond to short-lived species and so it is evident that the method shows promise in such studies.

The traces (3) to (6) illustrate the use of selected applied voltages and the way in which the results can be of value in the interpretation of results. For example, the cuts-in near − 0·1 V. are not observed until the applied voltage reaches − 0·6 V. Thus, these cuts-in are positively identified with the products of the six electron reduction of *p*-nitroaniline. Further evidence is then obtained by comparison with (8), which shows the oscillo-polarogram of *p*-phenylenediamine.

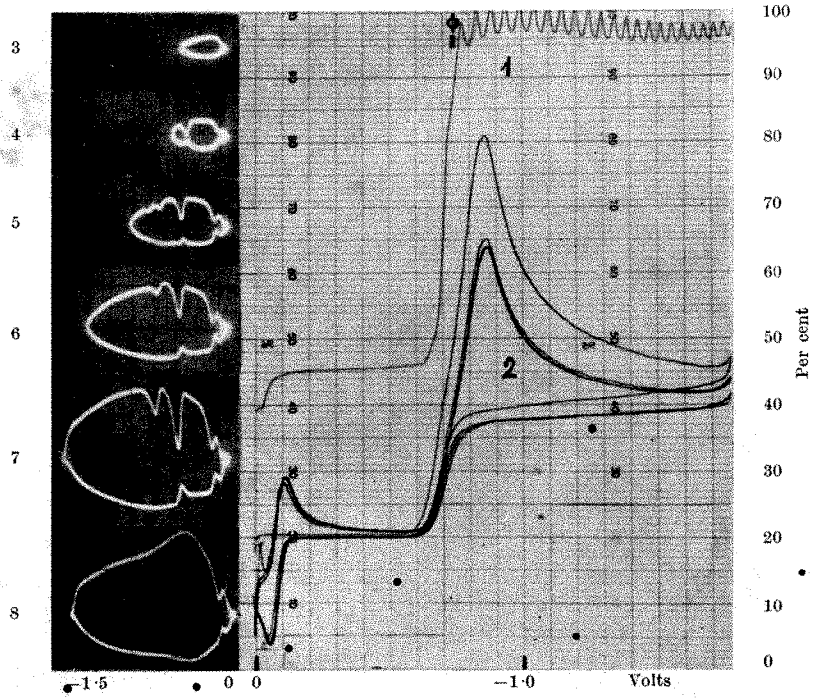

Fig. 1

It is evident that variable voltage oscillo-polarography with the hanging drop electrode offers considerable advantages in the interpretation of the sometimes very complicated traces which are often obtained with reducible organic solutions[3], and constitutes a new method of studying the properties of transient intermediates.

Standard Potential at 25° C. of the Silver–Silver Chloride Electrode in Formamide

FORMAMIDE is a very good solvent for many strong and medium weak acids. In order to determine their dissociation constants accurately by potentiometric measurements it is necessary to know the standard potential of a reference electrode with respect to the normal hydrogen electrode. Until recently, only the value of the cadmium–cadmium chloride electrode has been given in the literature[1]. We have been able to determine the standard potential of the silver–silver chloride electrode by the classical method using the following cell without liquid–liquid junction :

$$Pt, H_2/HCl(HCONH_2)/AgCl, Ag$$

Platinum electrodes were prepared according to Jones[2] and the silver–silver chloride electrodes by the electrolytic method[3,4]. (Both types of electrodes were reproducible within 0·5 mV.)

The potential E of this cell depends on the molality of hydrochloric acid, its mean activity coefficient and the standard electrode potential $E°$. The value of $E°$ may be found by using Hitchcock's method[5], which consists in extrapolating the auxiliary function $E' = E + 2k \log m - 2kAm^{1/2}$ to $m = 0$. Here $k = 2{,}3026 \cdot RT/F$ and $-Am^{1/2}$ is the first Debye–Hückel approximation of the logarithm of the mean activity coefficient. In the case of formamide, with dielectric constant[6] at 25° C. equal to 109·5, $2kA$ is equal to $3 \cdot 65 \times 10^{-2}$.

In all our experiments, the formamide ('Fluka', purum) was purified by vacuum distillation followed by two crystallizations and a fractional fusion. The physical constants of our final product ($T_f = 2{\cdot}9°$ C.; $n_D^{25} = 1{\cdot}4458$; $\varepsilon^{25} = 109{\cdot}5$) were in excellent agreement with the best values given in the literature[6, 7].

Solutions obtained by passing dry gaseous hydrogen chloride into the formamide could not be stored, even in an inert atmosphere. Decomposition of these solutions is probably due to hydrolysis of formamide by very small traces of water, this reaction being catalysed by hydrogen chloride[8]. Every solution used in the determination of $E°$ was therefore prepared directly in its cell immediately before measuring the potential, and the equilibrium values of these potentials, which changed slightly with time, were extrapolated to zero time. Nevertheless, the determination of the standard potential remained difficult as the preparation of the solutions was critical. Owing to the instability of the solutions, accuracy was not better than 1 mV. The molalities used ranged from $2{\cdot}38 \times 10^{-3}$ to $5{\cdot}164 \times 10^{-2}$.

Extrapolation of E' values by the method of least squares gave the following value for the standard potential (Fig. 1):

$$E° = 0{\cdot}204 \pm 0{\cdot}002 \text{ V.}$$

($0{\cdot}002$ is the mean standard deviation of the experimental points with respect to the calculated line.)

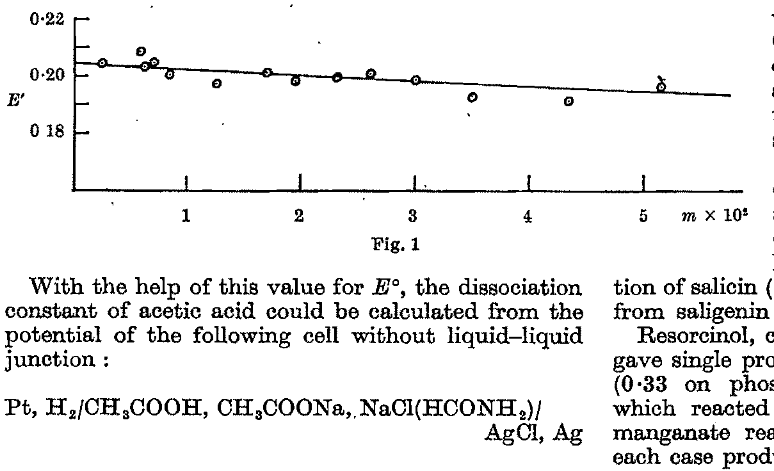

Fig. 1

With the help of this value for $E°$, the dissociation constant of acetic acid could be calculated from the potential of the following cell without liquid–liquid junction:

$$\mathrm{Pt,\ H_2/CH_3COOH,\ CH_3COONa,\ NaCl(HCONH_2)/AgCl,\ Ag}$$

Using the method of Harned and collaborators[9], we found $\log K_a = -6{\cdot}81 \pm 0{\cdot}01$ at 25° C., corresponding to a value[10] of the acidity function X equal to $0{\cdot}578$. This is in good agreement with the value predictable from those of other carboxylic acids in formamide and the X value of acetic acid in water[11].

Metabolism of Phenolic Compounds by the Broad Bean *Vicia faba*

PHENOLIC glycosides are common constituents of plant tissues but little is known about the biosynthesis of the glycosidic bond in these compounds. Bourquelot and Hérissey synthesized (*o*-hydroxybenzyl)-β-glucoside by incubating glucose with saligenin in the presence of emulsin[1], but it is unlikely that transglycosylation of this type is an important mechanism for the biosynthesis of glycosides *in vivo*. The formation of aryl glucosides by leaf disks infused with various phenols has been reported by Miwa *et al.*[2] and it appears that glucose-1-phosphate is involved in these reactions.

The stems of young bean shoots were immersed in aqueous solutions containing glucose (0·5 per cent (w/v) and a phenol (0·5 per cent w/v) and after 48 hr. the tissues were extracted with methanol and the extracts examined on paper chromatograms (butan-1-ol/ethanol/water (4 : 1 : 5, organic layer) solvent: ammoniacal silver nitrate[3], diazotized *p*-nitroaniline/sodium hydroxide[4] and periodate–permanganate[5] spray reagents). Some of the products were isolated in small amounts by chromatography on Whatman No. 3 paper and afterwards hydrolysed by an emulsin preparation.

The feeding of quinol and phloroglucinol gave rise to products which co-chromatographed with arbutin (R_F 0·44) and phlorin (R_F 0·35) respectively, and gave the same colour reactions with the diazo reagent as the authentic glycosides. Similarly, the compound obtained by feeding saligenin was indistinguishable from (*o*-hydroxybenzyl)-β-glucoside, and hydrolysis with emulsin yielded saligenin and glucose, this being further evidence for the presence of a β-glycosidic linkage. No evidence for the formation of salicin ((*o*-hydroxymethylphenyl)-β-glucoside) from saligenin could be obtained.

Resorcinol, catechol and hydroxyhydroquinone all gave single products (R_F values 0·51, 0·64 and 0·43 (0·33 on phosphate-buffered paper) respectively), which reacted with the diazo- and periodate-permanganate reagents. Hydrolysis with emulsin in each case produced glucose together with the phenol which had been administered to the shoot.

These results suggest that the mono-β-glucosides of catechol and resorcinol had been produced. The product obtained from hydroxyhydroquinone was probably (3,4-dihydroxyphenyl)-β-glucoside, as it showed a decreased rate of movement when subjected to chromatography on buffered paper, this being evidence for the presence of an *ene-diol* grouping[6]. Small amounts of an electrophoretically and chromatographically identical compound were also formed when young bean shoots were allowed to take up a solution of arbutin (1 per cent w/v). In this case, the arbutin was presumably hydroxylated by polyphenol oxidase.

Glucoside formation could not be demonstrated when phenol was used as a substrate and only traces of possible glucosides were produced using pyrogallol.

The biosynthesis of the glucosides was confined chiefly to the leaves and the activity was completely destroyed by grinding these tissues in the presence of 0·1 *M* phosphate buffer (*p*H 6·0). The synthetic activity of the isolated stems was negligible.

During the preparation of this communication, Hutchinson, Roy and Towers[7] reported glucoside formation by apple-leaf and leaves from a number of other plant species, when fed with phenols in the presence of D-glucose-^{14}C.

This study is being continued to determine the exact mechanism of formation of glucoside in the plant and to examine the biosynthesis and metabolism of the more complex phenolic glycosides containing two or more sugar units.

The interest shown by Prof. E. J. Bourne is very much appreciated.

A Paper Chromatography Method for the Determination of Suitable *p*H Values for the Extraction of Antibiotics

EXTRACTION methods are usually used for the isolation and purification of antibiotics soluble in organic solvents which are immiscible with water. This method can be applied if the partition coefficient of the antibiotic between the solvent and water is sufficiently large. The partition coefficient often depends on the *p*H value, particularly for acidic or basic compounds.

We have worked out a method for determining suitable conditions for the extraction of antibiotics by a *p*H chromatogram with the help of which we can also investigate the ionic character of the antibiotics. We use *p*H chromatograms when only cultures of the antibiotically active micro-organisms on Petri-dishes are available, that is, even before the crude substances have been isolated.

To prepare *p*H chromatograms we determine the solubility of the compounds by paper chromatography in 10 solvents[1]: distilled water, 3 per cent ammonium chloride (w/v), methanol, acetone, ethyl acetate saturated with water, *n*-butanol saturated with water, ether saturated with water, chloroform, benzene, petrol ether. Agar plugs, diameter 10 mm., cut from the micro-organism colonies, are placed 4 cm. from the lower end of 20 cm. × 1 cm. strips of Whatman No. 1 filter paper. After 15–30 min. the plugs are removed, the strips are dried in air, and chromatographed by the ascending technique using the solvents mentioned. After chromatographing, the strips are dried in air and placed on the surface of agar plates seeded with a suitable test-organism and detected bioautographically in the usual manner. After this, coloured prints on filter paper of the inhibition-zones can be obtained by our method[2].

The *p*H chromatograms are prepared as follows: nine sheets of Whatman No. 1 paper are buffered with McIlvain citrate–phosphate buffers of *p*H 2·2, 3, 4, 5, 6, 7 and 8 and with phosphate buffers of *p*H 9 and 10. After drying in air 20 cm. × 1 cm. strips of the buffered papers are cut, and the starting line and the upper line of the ascending solvents are marked 4 cm. and 19 cm. respectively from the lower end of the papers.

We use one strip of each of the nine buffered papers for the chromatography of every antibiotic. Agar plugs are put on the papers in the same way as was described for the method of selecting a suitable solvent. All nine strips are then chromatographed in the solvent which proved to be the most suitable. Development is stopped when the solvent front reaches the line 15 cm. from the start. After drying the chromatograms in air the bio-autographical detection method is used in the usual way.

The positions of the spots on the *p*H chromatograms are characteristic for every antibiotic. Acidic substances give spots farther from the starting line when chromatographed on papers buffered in the acidic range; the higher the *p*H the smaller the distance of these spots from the starting line. With basic substances the reverse is true. The distances of spots of neutral antibiotics are unaffected by *p*H. In this way the ionic character of an antibiotic can be determined from the overall characteristics of a complete *p*H chromatogram.

Among other things, the R_F values depend on the partition coefficient of the antibiotic between the mobile phase (organic solvent) and the non-mobile phase (water on paper)[3]. The extraction of a compound will be most successful at the *p*H value where this partition coefficient is greatest, that is, where the antibiotic spot on the *p*H chromatogram is farthest from the starting line. On the other hand, re-extraction from the organic solvent to water will proceed best at the *p*H value where the antibiotic spot remains on the starting line, that is, the *p*H at which it is most insoluble in the solvent used.

We have tested our method on a number of commercially available antibiotics using the solvents which are used in their industrial production. The results in all cases indicated extraction procedures absolutely identical with those applied in industry. A more detailed paper on this method will be published later[4].

As an example, a *p*H chromatogram of benzylpenicillin, developed by using amylacetate, is shown in Fig. 1. The appearance of the *p*H chromatogram confirms the acidic character of this compound and

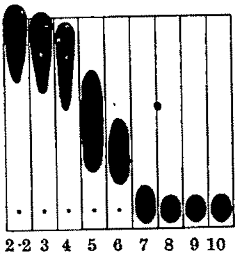

Fig. 1

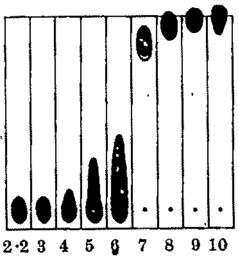

Fig. 2

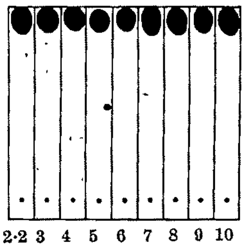

Fig. 3

Fig. 1. *p*H chromatogram of benzylpenicillin developed in amylacetate. Test organism, *Bacillus subtilis SDPC* 1 : 220

Fig. 2. *p*H chromatogram of erythromycin developed in amylacetate. Test organism, *Bacillus subtilis ATCC* 6633

Fig. 3. *p*H chromatogram of chloramphenicol developed in ethylacetate. Test organism, *Bacillus subtilis ATCC* 6633 indicates that the extraction of penicillin from water to amylacetate will be best at about pH 2. Similarly, the re-extraction from amylacetate to water will be best at pH 8. These results agree with known extraction and purification methods[5].

Figs. 2 and 3 show pH chromatograms for a basic antibiotic, erythromycin, and a neutral one, chloramphenicol. For erythromycin pH 9 and pH 4 are most suitable for extraction and re-extraction respectively[5]. The extraction of chloramphenicol is unaffected by pH [5,6].

This method has proved to be very helpful in research on new antibiotics.

Exogenous Sources of Urinary Phenol and Indole Acids

THE phenol and indole acids of human urine have been examined following the ingestion of bananas or coffee. Bananas were tested because of a report that they contain serotonin, norepinephrine, dopamine and possibly 3,4-dihydroxyphenylalanine[1]. Coffee was investigated because of an observation that vanillic acid is excreted following the ingestion of caffeic acid, but not coffee[2], and a suggestion that the excretion of vanillic acid may be related to norepinephrine metabolism and stress[3].

Two healthy adults were placed on a high-protein diet from which materials of plant origin were excluded in order to minimize the excretion of exogenous phenol and indole acids. Control urines were collected for 6 hr. on the second and third days. One subject then ingested 4 bananas (480 gm.) and the other 1,000 ml. of coffee percolated from 64 gm. of commercial, ground, roasted coffee beans. Urines were collected for the following 0–7 and 7–15 hr. periods. Extraction and two-dimensional paper chromatography were carried out as described previously[4,5]. The changes observed in the pattern of urinary phenol and indole acids are summarized in Table 1. The amounts of 5-hydroxyindoleacetic, 3-methoxy-4-hydroxy-D-mandelic and 3-methoxy-4-hydroxyphenylacetic acids were determined on paper chromatograms by visual comparison of spots obtained from appropriate aliquots of banana urine extracts and the authentic compounds.

It has been pointed out that measurement of urinary 5-hydroxyindoleacetic acid after ingestion of bananas could result in a diagnosis of carcinoid tumour[6]. The data in Table 1 show that excretion of this serotonin metabolite increased sharply in the first 7 hr. after ingestion but soon returned to normal. The diagnosis thus might vary with the time and duration of the urine collection after ingestion of bananas. The possibility of a diagnosis of pheochromocytoma also has been suggested[1]. The excretion of 3-methoxy-4-hydroxy-D-mandelic acid increased after ingestion of bananas, but the normal range[7] was not exceeded; if the output of this substance is used as an index of norepinephrine metabolism[7], an erroneous diagnosis is therefore unlikely. The excretion of 3-methoxy-4-hydroxyphenylacetic acid, which is a metabolite of 3,4-dihydroxyphenylalanine and dopamine, also remained within the normal range[8] after ingestion of bananas.

No other 5-hydroxyindole acids were detected in the banana urine extracts, even when volumes equivalent to 4 mgm. of creatinine were chromatographed. The occurrence in bananas of at least two 5′-hydroxyindoles besides serotonin has been mentioned[1]. The excretion of indoles No. 14 and 15 increased after banana ingestion; these compounds frequently are present in urines from institutionalized patients[5], but also have been observed in some normal urines.

The same m-hydroxyphenyl and 3-methoxy-4-hydroxyphenyl acids which were excreted after coffee (Table 1) also were detected in urine extracts

Table 1. PAPER CHROMATOGRAPHY OF URINARY INDOLE AND PHENOL ACIDS AFTER INGESTION OF BANANA OR COFFEE*

37	Unidentified	0	0	0	0	+++	+

* One + represents a spot diameter of $\frac{1}{4}$ in. The total amount of 5-hydroxyindoleacetic, 3-methoxy-4-hydroxy-D-mandelic, and 3-methoxy-4-hydroxyphenylacetic acids in each banana urine extract is corrected for endogenous excretion, which was determined from control urines.

† Numbers refer to chromatographic maps of urinary phenols (ref. 4) and indoles (ref. 5).

‡ These compounds give blue spots with p-dimethylaminobenzaldehyde after several hours, and are probably the ones designated as indoles No. 11 and 28 in a previous report (ref. 5).

after ingestion of caffeic or ferulic acids. The results differ in some respects from those of Booth *et al.*[2], who first reported the unusual formation of these groups of metabolites from caffeic and ferulic acids. These workers noted that only *m*-hydroxyhippuric acid and *m*-coumaric glucuronide, and none of the other caffeic acid metabolites, were excreted after ingestion of 'instant' or caffeine-free 'soluble' coffee. Their observation of fewer metabolites may reflect a loss or change of some components during manufacture of 'soluble' coffee. The hydracrylic acids (phenols No. 2 and 18) were not recorded as metabolites by Booth *et al.*[2]. These compounds are converted easily to the corresponding acrylic acids, however, and could have been destroyed under the different conditions of processing.

Vanillic acid and the other related exogenous 3-methoxy-4-hydroxyphenyl acids have been observed in many human urines[4]. Metabolic precursors are also present in plant materials other than coffee, such as fruits and vegetables[2], and natural vanilla flavour is added to some commercial foods. A suggestion that, on an unrestricted diet, the excretion of vanillic acid may be related to norepinephrine metabolism and stress[3] therefore seems unjustified.

This research was generously supported by a grant from the Ford Foundation.

Rennin Coagulation of Enzymatically Dephosphorylated Casein

MANY of the properties of milk depend on the existence of large aggregates of casein[1], the 'molecular' weights of which are in the region of 10^6. When calcium-binding substances such as citrate or oxalate are added, these aggregates are rapidly reduced in size[2] to a 'molecular' weight of about 10^5, the specific value being highly dependent on *p*H, temperature and ionic strength[3]. The mechanism whereby calcium effects the formation of the aggregates is unknown, but it has often been assumed that the first step is combination with the phosphate groups of casein, and it has been suggested[4] that the calcium ions might cross-link adjacent casein molecules. In recent years it has been found that various phosphatases will catalyse the removal of phosphate groups from casein under mild conditions of *p*H and temperature[5,6]. Thus enzymatic dephosphorylation should be a useful tool in studying the role of casein-bound phosphate in the reactions of milk dependent on calcium. The clotting of milk by the enzyme rennin is dependent on calcium[1], and is a reaction which lends itself to precise study.

Several phosphatases were investigated; potato phosphatase was chosen for its apparent freedom from proteinases and for its ability to act on casein as it exists in milk, as well as on solutions of isolated casein. This phosphatase was purified by a slight modification of Kornberg's method (Horecker, B. L., private communication). The final preparation had a specific activity of $1 \cdot 7 \times 10^5$ units/mgm. protein and showed a 1,200-fold increase (on a protein basis) over the original extract. (One unit releases 1 μgm. phosphorus/hr. from *p*-nitrophenyl phosphate in the following conditions: 0·02 M substrate; 0·08 M acetate buffer (acetic acid/sodium acetate), *p*H 5·0; 0·004 M magnesium chloride; incubated at 37° C. A solution containing 1 gm. bovine albumin per dl. was used as a diluent for the enzyme.)

Preliminary studies showed that the rennin coagulation-time of milk could be increased markedly by treatment with potato phosphatase. In some experiments coagulation did not occur even after 100 times the normal amount of rennin had been added. It was then decided to make a quantitative study of this phenomenon, and for this purpose it was thought advisable to work with isolated casein. In order to obtain reproducible results it was necessary to follow a carefully controlled procedure both in the preparation of dephosphorylated casein and in the measurement of rennin coagulation-times. Depending on the degree of dephosphorylation desired, varying amounts of phosphatase (200–1,000 units per ml. of casein solution) were added to a 5 gm./dl. solution of bovine casein (prepared by the method of Van Slyke and Baker[7]), which was then incubated at 37° C. (Solution of the casein was achieved by the slow addition of 0·2 N sodium hydroxide to a suspension of the casein in distilled water; the *p*H did not exceed 8 in the process, and the final *p*H was 6·8.) After 0–5 hr., an aliquot was removed for the assay of inorganic phosphate, and the remainder was diluted with 8 volumes of cold (0–5° C.) distilled water and precipitated by the slow addition of 1 M acetic acid. The precipitate was separated by filtration through a sintered glass funnel, then washed 2–5 times with cold distilled water, twice with cold (−13° C.) 95 per cent ethanol and twice with cold (−13° C.) ether. Finally, it was ground in a mortar and dried *in vacuo* over calcium chloride. The product was free from phosphatase activity. For studying their coagulation by rennin, the samples of dephosphorylated casein were dissolved as before to give a solution of 0·3 gm./dl. and then twice dialysed for at least 2·5 hr. at 0–5° C. against 18 volumes of a *p*H 6·8 buffer[8] containing $3 \cdot 66 \times 10^{-2}\ M$ cacodylic acid, $2 \cdot 94 \times 10^{-2}\ M$ triethanolamine, and sufficient calcium chloride to give the desired concentration of calcium. After dialysis the solutions were diluted with buffer to give a final concentration of protein of 0·24 gm./dl. Coagulation times[9] were measured on duplicate samples after 10–15 min. equilibration at 30° C. Crystalline rennin from calves was used (Ernstrom, C. A., unpublished work).

Fig. 1 shows the results obtained with one set of samples of dephosphorylated casein. As the percentage dephosphorylation is increased, the time required for coagulation by rennin first increases and then passes through a maximum. The same behaviour is observed at all three levels of calcium, but the effect is more striking at the lower levels. No coagulation was observed in 0·011 M calcium chloride for the samples with intermediate degrees of dephosphorylation. Another set of samples of dephos-

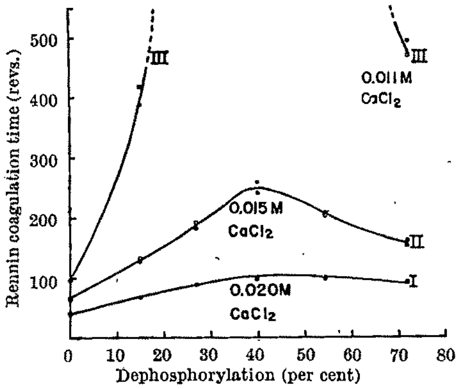

Fig. 1. The relation between percentage dephosphorylation of of bovine casein and the time required for clotting by rennin, at three concentrations of calcium. 10 ml. of casein solution was brought to the temperature of the bath (30° C.), and 1 ml. of rennin ($5 \cdot 6 \times 10^{-4}$ mgm. of rennin nitrogen) was added. Samples were rotated at 16·2 r.p.m. The concentrations of calcium given are those of the buffers against which the samples were dialysed

phorylated casein showed the same behaviour as that in Fig. 1 but gave slightly different values for the coagulation-times. The fact that the curves pass through a maximum suggests that more than one effect of dephosphorylation is present; it is likely that the increase in isoelectric point on dephosphorylation tends to produce shorter coagulation times.

'Solubilization' of a Cytochrome *b* Component from *Micrococcus lysodeikticus*

IN an earlier communication[1] we reported some preliminary observations on a cytochrome *b* component of *Micrococcus lysodeikticus*, strain N.C.T.C. 2665. The cytochrome was separated to some extent from the cytochromes *a* and *c* which were also present, but it remained attached to particles which were thrown down by centrifugation at 20,000*g*.

In further experiments, we have found that the cytochrome can be 'solubilized' by treatment of the particulate preparation with a 1 per cent solution of 'Cetrimide' (B.P.). Centrifugation at 20,000*g* at this stage separated a small deposit which contained some cytochrome *c*. Further purification of the cytochrome *b* component was achieved by fractional precipitation from the supernatant by addition of ammonium sulphate. Between 20–40 per cent (w/v) ammonium sulphate, the small quantity of residual cytochrome *c* was precipitated. The cytochrome *b* component came down as a red, gelatinous precipitate at ammonium sulphate concentrations of 40–60 per cent (w/v). This material was apparently soluble in 0·04 *M* phosphate buffer at *p*H 7. The solution obtained was dialysed for 24 hr. against running tap-water, and during this time precipitation of a yellow pigment occurred, the absorption spectrum of which suggested that it might be a carotenoid. The maxima in petroleum ether, 415 mμ, 435 mμ and 465 mμ, corresponded to the wave-lengths recently reported[2,3]. The precipitate was filtered off and the filtrate was allowed to stand in the cold. More of the yellow pigment separated over a period of 48 hr., but no further precipitation occurred during the subsequent 72 hr.

The remaining solution was examined spectrophotometrically, after reduction by addition of solid sodium dithionite, and peaks corresponding to a cytochrome of the *b*-group were found. The absorption maxima of this component were at 558 mμ, a small peak at approximately 525 mμ and a Soret peak at 529–530 mμ; there was no evidence of residual cytochrome *c*. It appears, therefore, that the component should be regarded as a cytochrome b_1. The maximum at 558 mμ differs slightly from that found earlier with cruder preparations in glycerol, which showed a 'flat' peak extending from 560 mμ to 563 mμ. These observations have been repeated, and the slight difference has been confirmed. Whether it is due to the presence of an extra component in the crude preparations or to a slight shift due to different optical or physico-chemical conditions is not yet certain. Because of the residual light-scattering with the cruder materials, the readings were necessarily less precise than with the clear solutions which were later available.

The solutions obtained by the method described still contained some yellow carotenoid pigment which could not be extracted with petroleum ether. The pigment was, however, extractable with chloroform or butanol, but the cytochrome b_1 was damaged by this treatment.

These observations suggest that at least some of the carotenoid is conjugated with a protein, and while it is possible that this might be the protein moiety of cytochrome b_1 itself, we have no direct evidence for this.

We wish to thank the Medical Research Council for a grant, and Dr. D. W. Henderson, of the Microbiological Research Department, Porton, who kindly arranged the bulk culture of *Micrococcus lysodeikticus*.

Occurrence of Poly-β-Hydroxybutyric Acid in Aerobic Gram-Negative Bacteria

DURING an examination of the metabolic products of an unidentified purple-pigmented pseudomonad, a fraction, soluble in chloroform and insoluble in ether, was found to comprise 30 per cent of the dry cell weight. The material was isolated as a colourless solid, m.p. 168° C., which gave on alkaline hydrolysis a 70 per cent yield of crotonic acid. (Identified by m.p., mixed m.p. and preparation of the anilide and *p*-bromphenacyl ester.) The crotonic acid could also be obtained in 60–70 per cent yield by destructive distillation of the original solid. It was thought likely that the solid was a β-hydroxybutyric acid polymeric ester and this was confirmed by infra-red spectroscopy (ref. 1 and Farmer, V. C., personal communication) and by analysis (found, per cent; C, 55·1; H, 7·1. Calculated for $(C_4H_6O_2)_n$: C, 55·8; H, 6·8). Similar polymers have been described from *Bacillus megaterium*[2], *Azotobacter chroococcum*[3] and *Micrococcus halodenitrificans*[4].

The unidentified pseudomonad (*HCC*, *B* 175)[5], which was typical of a group isolated from Trinidad soils, was stained for the presence of 'fat' by the method of Burdon[6], using an alcoholic solution of sudan black *B* (G. T. Gurr, Ltd., London). The cells were found to be intensely sudanophilic, as was the isolated polymer. A survey was then made for the presence of sudanophilic material in a wide range of bacteria grown on an agar medium containing glucose or glycerol as major source of carbon. All those which stained strongly and a number which did not stain were further examined. Shake flask cultures or cultures from a 2-litre aerated fermenter were centrifuged, and the dried cells extracted with hot chloroform. The chloroform extract was filtered into 3 volumes of ether, and the formation of a flocculent white precipitate was taken as being indicative of the presence of poly-β-hydroxybutyric acid. No organism lacking in sudanophilic substance gave this reaction, although some containing sudanophilic substance did not contain the polymer and presumably contained conventional lipids. The presence of poly-β-hydroxybutyric acid was confirmed in representative cultures by destructive distillation of the solid and isolation of crotonic acid, which was in every case obtained in 60–70 per cent yield. Some results of the survey are shown in Table 1.

Poly-β-hydroxybutyric acid was not detected in the following genera and species of bacteria: *Proteus*, *Flavobacterium*, *Aerobacter aerogenes* (2 strains), *Escherichia coli* (2 strains), *Serratia marcescens* (5 strains), *Xanthomonas vasculorum* (3 strains) and *Protaminobacter rubrum* (*NCIB* 2879). The polymer has thus far not been detected in numerous pigmented and non-pigmented pseudomonads, other than those listed in Table 1; they include *Pseudomonas aeruginosa*, *Ps. fluorescens*, *Ps. aureofaciens*[8,9], *Ps. chlororaphis* and *Ps. lemonnieri*[10].

The fact that the polymer was found in all the chromobacteria examined (Table 1) is of interest in view of the observation of Sneath[11] in a taxonomic study of *Chromobacterium*, that the mesophilic chromobacteria, especially, contain considerable deposits of 'fat'.

Root nodules of several leguminous plants were examined in addition to cultures of *Rhizobium*. Acetone-dried nodules from *Mimosa pudica* were found to contain 6 per cent of poly-β-hydroxybutyric acid. This substance was also detected in nodules of a *Pueraria* sp., but apparently in smaller amount. Crushed nodules from both plants were stained with sudan black *B* and the bacteroids found to contain much sudanophilic material.

Our survey has been confined mainly to aerobic Gram-negative bacteria. Poly-β-hydroxybutyric acid has not, however, so far been detected in *Streptomyces* or *Lactobacillus*, in the anaerobe, *Clostridium acetobutylicum*, or in several yeast-like fungi.

We have isolated from sea water a salt-tolerant Gram-negative rod capable of forming in artificial culture large quantities of poly-β-hydroxybutyric acid. We have not yet examined cultures of *Spirillum* for the presence of poly-β-hydroxybutyric acid, though the evidence of Lewis[12] on the cytology of this genus leads us to suspect that some spiral bacteria contain large deposits of this substance.

The cultural conditions affecting yields of polymer and the enzymic mechanism of synthesis are being studied further and will be reported elsewhere. It is obvious that there are many cases in the literature where deposits of poly-β-hydroxybutyric acid have been confused with true lipids or even as in the case

Table 1

Culture	Source and strain No.*	Culture medium (carbohydrate and organic nitrogen sources only)	Poly-β-hydroxybutyric polymer (percentage of cell dry weight)	Melting point (° C.)
Chromobacterium violaceum	*NCIB* 8182	2 per cent glucose/peptone (68 hr.)	37	164

Separation of Anthocyanin and Leuco-anthocyanin in Flowers of *Camellia japonica*

Bate-Smith[1] observed that a methanol extract of white flowers of *Camellia japonica* turned red after heating with dilute hydrochloric acid. This suggests that leuco-anthocyanin is present in the white flowers. By the same procedure I found that red flowers of several horticultural varieties of *C. japonica* contained leuco-anthocyanin yielding cyanidin, as well as a glycoside of cyanidin.

A methanol-hydrochloric acid extract of red flowers of one of the varieties, Shikainami, was paper-chromatographed with the solvents butanol/concentrated hydrochloric acid/water (5 : 1 : 4, v/v) and 80 per cent formic acid/concentrated hydrochloric acid/water (5 : 1 : 4, v/v)[2]. As controls, chrysanthemin and cyanin were chromatographed on the same paper. R_F values were estimated as 0·24, 0·27 and 0·09, respectively, with the former solvent; and 0·53, 0·58 and 0·75 with the latter. The hydrolysate of the extract and cyanidin were then co-chromatographed using the second solvent. R_F values of the samples were identical, that is 0·20. No other spots of anthocyanin or anthocyanidin could be detected on the chromatograms.

The separation of leuco-anthocyanin from anthocyanin was carried out as follows. The red flowers (20 gm. fresh weight) were macerated with 150 ml. methanol and filtered. The filtrate was concentrated *in vacuo* at 30° C. until 15 ml. of a dark purplish-red syrup remained. The syrup was passed through a resin column (1·3 × 12 cm.) packed with 'Amberlite' *IRC*–120 (H form). The anthocyanin was found to be adsorbed quantitatively on the resin and the filtrate from the column was slightly orange. The filtrate was neutralized with 0·1 *N* sodium hydroxide and saturated with sodium chloride. Then it was exhaustively shaken with 30 ml. portions of ethyl acetate until the aqueous layer remained orange-brown after heating with propanol-hydrochloric acid[3]. The combined colourless ethyl acetate extracts were dried with sodium sulphate and evaporated *in vacuo* until a slightly pink-coloured residue remained. The residue was dissolved in 7 per cent hydrochloric acid and heated in a water-bath until a dark red colour appeared. The red matter was transferred by partition to a small amount of amyl alcohol, and the alcoholic layer was paper-chromatographed, in parallel with cyanidin, with formic acid/hydrochloric acid as solvent. The R_F value of the former was 0·19 (accompanied by brownish trail), and that of the latter (cyanidin) 0·20. This indicates that the leuco-pigment is sugar-free and should be regarded as leuco-cyanidin[4]. Extract of red flowers of the other variety, Somekawa, showed almost the same results.

Thus, it appears that flowers of some varieties of *C. japonica* contain leuco-anthocyanin, irrespective of their flower colours.

Incorporation of Orotic Acid-^{14}C and Lysine-^{14}C in Regenerating Single Nerve Cells

Experiments on the cytoscale and also, by inference, on the tissue and macroscale have demonstrated that proteins, lipids and ribonucleic acid in the central nervous system are in a dynamic state[1–3]. The production and metabolism of these substances are apparently promoted by increased functional demands.

The process of peripheral nerve regeneration can be repeated several times during the life-cycle of the organism. The production of proteins, lipids and ribonucleic acid per nerve cell has been studied by quantitative cytochemical methods during regeneration in hypoglossal cells[4]; the latent out-growth and maturation period could clearly be distinguished cytochemically. The results reported here demonstrate the incorporation of lysine-^{14}C into the nerve-cell proteins, and orotic acid-^{14}C into the ribonucleic acid of nerve cells during regeneration.

Nerve cells belonging to the hypoglossal nucleus in rabbits were used. The nerve was crushed with cooled forceps and 0·01 mc. L-lysine-^{14}C or orotic acid-^{14}C was injected intracisternally. The rabbits treated with lysine were killed 30 min. after the injection, and the others 24 hr. after the administration of orotic acid. The nerve cells were sampled by dissecting by hand under a preparation microscope. Fig. 1 shows some fresh hypoglossal cells, dissected out and photographed in the phase-contrast microscope. Five to ten cells were used for each measurement. The cells were transferred rapidly from the fresh tissue to 0·25 *M* sucrose, freed from surrounding glial cells, placed on a holder and treated with 1 *N* cold perchloric acid for 30 sec., and carefully washed and dried. The hypoglossal control cells then weigh on average 2,200 µµgm., that is 2,000 µµgm. protein and about 10 per cent ribonucleic acid. The activity was measured with a special Geiger microtube with a window thickness of 1·5 mgm./cm.^{2}, provided

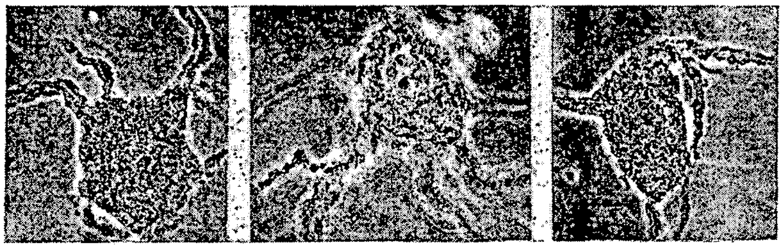

Fig. 1. Fresh hypoglossal cells from the rabbit photographed in the phase-contrast microscope in 0·25 *M* sucrose. Note the synaptic knobs as small granules on the surface of the cells

with an anti-coincidence shield. The background activity of the tube at the measuring was only 1 count/min. The results obtained are related below to those found in the quantitative study on the same type of material[4].

During the 'latent period' a small part of the nerve close to the site of the crush degenerates. The amount of protein per nerve cell was found to decrease by 30–40 per cent during this stage. The cell volume began to increase, and morphologically chromatolytic areas could be found within the cell. The incorporation of lysine-^{14}C into regenerating cells exceeded that into control cells by 70 per cent (Table 1).

Table 1. Uptake of Lysine-^{14}C by Regenerating Isolated Nerve Cells

Days after operation	Activity ratio operated cell/control cell
2	1·7
9	3·2
21	1·5
207	1·4

Lajtha *et al.*[2] and Furst *et al.*[5] have pointed out that lysine is especially useful in the study of brain proteins. In experiments of short duration the incorporation into rapidly metabolized proteins is primarily measured. The presence of free lysine can be expected to influence the result slightly, but it is important to note that this factor does not affect the conclusion that the activity found in our experiments is a measure of the metabolic activity of the cell proteins.

The protein decrease per cell and the increased incorporation of lysine into the cell proteins show that the protein loss during the latent period is not compensated by intracellular production, in spite of increased protein synthesis.

During the next stage, 3–12 days after the crush, the thin axons rapidly grow out to re-establish contact with the effector organ. This 'out-growth period' is characterized by a 100 per cent increase in the proteins per cell. The incorporation of lysine into the regenerating cells was found to increase by 200 per cent. During the same period no significant change occurred in the amount of ribonucleic acid per cell; this remained at 200 $\mu\mu$gm. But a most significant alteration occurs in the aggregation of the cytoplasmic ribonucleic acid which becomes finely dispersed, with the typical appearance of chromatolysis. During the first day after the crush no difference in the orotic acid-^{14}C incorporation was found in control and regenerating nerve cells. On the eighth day, however, when chromatolysis was pronounced, the incorporation increased by 100 per cent in the regenerating cells.

Thus, the nerve cell showing typical retrograde changes during regeneration is characterized by an intracellular concentration decrease and a considerable increase in the rate of protein metabolism. Furthermore, the orotic acid incorporation and the change in aggregation of ribonucleic acid indicate that the ribonucleic acid of the chromatolytic nerve cell is transformed from a less active to a more active form.

During the 'maturation period' the size of the axon increases. The incorporation of lysine indicates that the increase in protein metabolism per nerve cell will continue during this stage. Fischer *et al.*[6] found that regenerating hypoglossal cells 14 days after a nerve crush incorporated more methionine-^{35}S per unit area than did the control cells.

A detailed account of the experiments will be published elsewhere. The studies have been supported by grants from the Rockefeller Foundation and from the Swedish Medical Research Council.

Influence of Linoleic and Linolenic Acids on Symptoms of Vitamin E Deficiency in Chicks

EXUDATIVE diathesis and encephalomalacia, two of the outstanding symptoms of vitamin E deficiency in chicks, are much promoted by dietary polyenoic fatty acids[1,2]. It has recently been shown[3] that, in certain circumstances, the former can occur even when the diet is free from polyenoic fatty acids; further, it can be prevented by a trace of 'Selenite'[4,5]. To our knowledge, encephalomalacia has never been observed with diets not containing polyenoic fatty acids, and this symptom is not prevented by 'Selenite'[6].

The differences in the etiology of exudative diathesis and encephalomalacia clearly call for further study. We have therefore studied the influence of two different polyenoic fatty acids, namely, linoleic and linolenic, on the two symptoms.

The composition of the vitamin E-free basal diet used is shown in Table 1. Analyses of the yeast and gelatine (petroleum ether extraction from acidified alkali-hydrolysate and subsequent alkali-isomerization) showed that the amount of polyenoic fatty acids in this diet was less than 0·016 per cent.

The ethyl esters of linoleic and linolenic acids were added daily at a level of 1·5 per cent to the basal diet. (In our Department it has been found that Fleischmann yeast, Type 50*B*, has a powerful antioxidant effect, so that poly-unsaturated fatty acids incor-

Table 1. Composition of Basal Diet (gm./100 gm.)

Fleischmann yeast, type 50*B*	40
Gelatine	3
Salt mixture (ref. 7)	5·17
Vitamin mixture (ref. 7)	0·10
Choline chloride	0·20
Sucrose	51·53

Plus 0·001 gm. dicalcium salt of 2-methyl-1,4-naphthohydroquinone diphosphoric acid ester ('Synkavit', Roche) per 100 gm. diet. Vitamins A and D_3 were given in aqueous solution (ref. 7), 0·1 ml. twice a week each animal, corresponding to 250 I.U. vitamin A and 20 I.U. vitamin D_3 a day.

porated in a diet of the composition mentioned are only slightly autoxidized when left on open trays for a period of 24 hr. at 26° C. This is contrary to what happens when casein is the source of protein in the diet. The ethyl esters of linoleic and linolenic acids were obtained from the Hormel Institute, Austin, Minn. The linolenate, which had been prepared via the hexabromide, contained some trans-fatty acids as shown by infra-red spectrophotometry.)

Chicks which had received a commercial chicken mash low in vitamin E during the first two weeks after hatching[7] and thereafter were reared on the experimental diets showed the symptoms listed in Table 2 within 28 days.

It is evident that exudative diathesis was produced by both the two polyenoic fatty acids examined, but encephalomalacia only occurred with linoleic acid.

About one-third of the chicks with exudates in the linoleate and linolenate groups had peroxides (values ranging from 3·8 to 49·3) in the affected fat tissue. No peroxides could be detected in the fat tissue of the chicks which had no exudates.

The fact that the incidence and severity of exudative diathesis was less in the linoleate group than in the linolenate group may be due to the fact that, in the linoleate group, 11 out of the 12 chicks died from encephalomalacia before the end of the experimental period. In the linolenate group, however, 9 out of 12 chicks lived through the entire experimental period.

The observation that linoleic acid produces encephalomalacia in the absence of vitamin E is in accordance with the results of earlier experiments in which peanut oil treated with 'Filtrol' was used as addition to an otherwise fat-free and vitamin E – free diet[8].

The present experiments suggest that a suitable diet for producing encephalomalacia may be one containing linoleic acid and a trace of 'Selenite' in order to prevent simultaneous occurrence of exudative diathesis.

Since dietary linoleic acid is, to a large extent, converted into tetraenoic (arachidonic) acid, it is possible that linoleate exerts its encephalomalacia producing effect via arachidonate. Earlier studies[2] have demonstrated that the fraction of hog liver fatty acids which remains in solution in acetone at −76° C. has a powerful effect in provoking encephalomalacia. This fraction is known to contain arachidonic acid. Addition of cholesterol to a diet producing encephalomalacia decreases the incidence of encephalomalacia and favours the development of exudative diathesis[1]. This may be related to the observation that, when added to a diet containing linoleic acid, cholesterol decreases the deposition of tetraenoic acid in the liver[9]. However, further studies are required to investigate more fully the part played by tetraenoic and other polyenoic fatty acids as well as their isomers in vitamin E-deficiency symptoms.

Table 2. Experimental Feeding Period: 28 Days

Addition to basal diet	No. of chicks in group		No. of chicks with exudative diathesis	No. of chicks with encephalomalacia
	at beginning of experiment	alive at end of experiment		
None	12	12	0	0
1·5 per cent ethyl linoleate	12	1	3*	11
1·5 per cent ethyl linolenate	12	9	7†	0

* None of the exudates were so severe that they affected the general behaviour of the chicks.

† Four of these chicks had very severe exudates.

The dietary level of linoleic acid used in the present experiments corresponds approximately to the amount of this acid in a diet containing 60 per cent torula yeast '3*N*' without added fat[6]. Nevertheless, such a torula yeast diet produces only a few cases of encephalomalacia and a very high incidence of exudative diathesis. This is suggestive of the occurrence in torula yeast of principles counteracting encephalomalacia and favouring exudative diathesis. The existence of factors provoking exudate, in addition to the particularly effective polyenoic fatty acids has already been proved, since we have found that silver acetate added at a level of 20 p.p.m. silver ions to the basal diets mentioned and certain other basal diets has a pro-exudative effect.

Inability of Epinephrine to protect Rhode Island Chicks against the Lethal Action of X-Rays

Stearner *et al.* have observed that young White Leghorn chicks[1] are protected against radiation mortality by epinephrine in solution in oil. I have repeated these experiments with Rhode Island chicks, which are more radio-resistant than White Leghorns, reproducing Stearner's conditions so far as the number and time of injections and the amounts of epinephrine injected are concerned.

Twenty-one day old Rhode Island chicks were irradiated with 2,000-r. X-rays, administered at a dosage-rate of 100r./min. An oily solution of epinephrine (Parke Davis) was injected into the pectoral muscles 5 min. before and 5 min. after irradiation, 2·5 or 5 mgm./kgm. being injected each time.

I have also used epinephrine, ephedrine and privine (2-naphthyl-(1′)-methyl-imidazoline nitrate) in aqueous solution.

Table 1. EFFECT OF INTRAMUSCULAR INJECTIONS OF EPINEPHRINE IN PEANUT OIL ON INITIAL AND DELAYED MORTALITY OF X-IRRADIATED RHODE ISLAND CHICKS
(Total dose, 2,000 r., dosage-rate 100 r./min.)

Dose of epinephrine before and after X-rays (mgm./kgm.)	No. of animals	Total mortality at 30 days (per cent)	Initial mortality at 0–2 days (per cent)	Delayed mortality at 3–30 days (per cent)
Controls	25	84	64	20
2·5	20	85*	60*	25*
5	25	80*	72*	8*

* Variations not statistically significant

After 30 days, the mortality among the irradiated chicks treated with epinephrine in oil was the same as that of the control chicks irradiated with 2,000 r. (Table 1). Initial mortality (0–2 days) was higher in animals injected with 5 mgm. of epinephrine in oil per kgm. body-weight than in irradiated controls.

Although I used the same technique as Stearner and his collaborators for injecting epinephrine obtained from the same source, I have been unable to reproduce with Rhode Island chicks the results obtained by these workers with White Leghorns[2]. My techniques differed from theirs in that I used a higher dosage-rate of irradiation (100 r./min.) and a higher total dose, and in the age and the race of the chicks employed. However, in my experiments a total dose of 2,000 r. administered to my control chicks gave a mortality after 30 days approximately equal to that found by the American authors[1] after 15 days in White Leghorns irradiated with 1,000 r. Not only did I find that no protection was afforded by epinephrine dissolved in oil, but mortality was accelerated among irradiated chicks when 5 mgm./kgm. was administered before and after irradiation.

Some assays have shown that epinephrine and ephedrine in aqueous solution have no protective action[3]. Privine, which is also a vasoconstrictor in the case of mammals, is very toxic (apathy, paralysis, dyspnea) and totally ineffective in the case of X-ray sickness in chicks.

Effect of Analogues of Glutathione on the Feeding Reaction of Hydra

LOOMIS[1] has shown that the 'feeding reaction' which *Hydra littoralis* exhibit after they have captured living prey is controlled chemically: the feeding reaction is elicited by glutathione released from the prey. In the absence of prey, glutathione induces writhing of the tentacles and, in higher concentrations, glutathione causes the hydra to retract the tentacles. These effects were found to be more marked when the hydra had previously been starved for several days. Loomis found that the effect was quite specific and that even the closely related aspartathione was inactive. Two analogues of glutathione (ophthalmic acid and norophthalmic acid) have recently been isolated from calf lens[2-4]; they differ structurally from glutathione in that the SH group is replaced by a CH_3 group in ophthalmic acid, and an H atom in norophthalmic acid. We have now found that these analogues of glutathione also elicit the feeding reactions in *Hydra littoralis*.

The experimental conditions were the same as those used by Loomis. The hydra were kept in a modified tap water medium[5], and were starved for five days before each experiment; during starvation the medium was renewed daily. The results are shown in Table 1; the activity is classified as strongly marked (++), clearly discernible (+), doubtful (±) or absent (0). Ophthalmic acid is seen to be more active, and norophthalmic acid less active, than glutathione, which itself is active at a concentration of only 10^{-5} *M*. Since the analogues do not contain an SH group, it follows that the SH group of glutathione is here unnecessary; thus for the first time a specific biological effect of glutathione is found to be unrelated to the SH group, but strongly dependent upon the molecular size and shape.

Table 1. ACTIVITIES OF GLUTATHIONE, OPHTHALMIC ACID AND NOROPHTHALMIC ACID IN ELICITING THE FEEDING REACTION OF *Hydra littoralis*

Concentration (*M*)	Activity*		
	Glutathione	Ophthalmic acid	Norophthalmic acid
10^{-3}	++	++	+
10^{-4}	+	++	±
10^{-5}	+	++	0
10^{-6}	0	+	
10^{-7}	0	0	

* See text for description of categories.

Two analogues of glutathione which do not occur naturally have also been tested; these are inactive themselves, but inhibit the elicitation of the feeding response by glutathione or ophthalmic acid. The results for the adduct obtained from glutathione and N-ethylmaleimide are shown in Table 2; the activities are classified as described above. The other synthetic inhibitor is the sulphonic acid, γ-L-glutamyl-L-sulphoalanylglycine, and this gave the same pattern of results. Furthermore, similar results were obtained when these synthetic inhibitors were tested against the feeding reaction elicited by ophthalmic acid; norophthalmic acid, itself less active, was more readily inhibited. Thus, of the analogues of glutathione, the two naturally occurring ones are active, but the two synthetic ones are inactive and inhibitory. In the glyoxalase reaction, however, where glutathione is a coenzyme and its SH group enters into the reaction, both the naturally occurring and synthetic analogues are inhibitors[6,7].

Ophthalmic acid was not detected in the *Artemia* on which the hydra fed, so that there is no evidence that the feeding reaction elicited by ophthalmic acid occurs under ordinary conditions.

We are greatly indebted to Dr. W. F. Loomis for supplying us with *Hydra littoralis*; we are also

Table 2. ACTIVITY OF GLUTATHIONE IN THE PRESENCE OF AN INHIBITOR (THE ADDUCT OF GLUTATHIONE AND N-ETHYLMALEIMIDE) IN ELICITING THE FEEDING REACTION OF *Hydra littoralis*

Adrenal Activity in Subjects with Complete Transverse Lesions of the Spinal Cord

HUMAN subjects with complete transverse lesions of the upper thoracic and cervical spinal cords show some features of hypoactivity of the adrenal medulla and of the adrenal cortex: the concentration of adrenaline in the peripheral plasma[1] and the excretion of 17-ketogenic steroids in the urine[2] are both significantly lower than normal.

Since eosinophilia is commonly found in conditions of adrenal insufficiency it was of some interest to measure the number of eosinophils in the blood of patients with complete transverse lesions of the upper thoracic and cervical cord, that is above the fifth thoracic vertebra (T.5), and to compare them with the values found in patients with cord lesions below T.5. This latter group of patients showed no features of adrenal hypoactivity. Eosinophil counts were carried out by the method of Pilot[3].

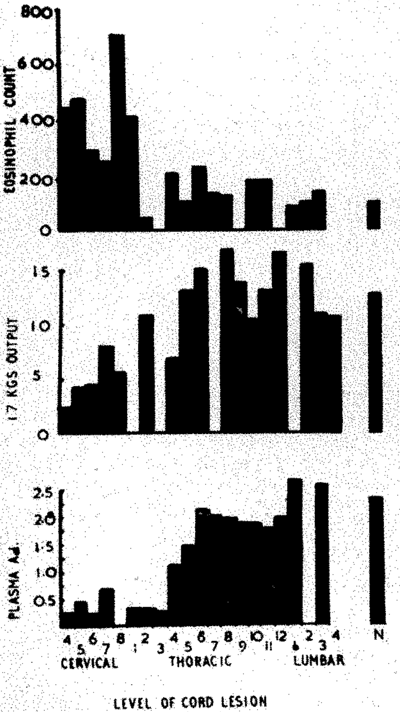

Fig. 1. Mean values of eosinophil count in cells per mm.^{3} (top), 17-ketogenic steroid excretion in mgm. per 24 hr. (middle), and plasma adrenaline in μgm./l. (bottom). The columns marked 'N' show the mean results of groups of normal control subjects

Thirteen out of twenty-one patients with complete spinal cord lesions above T.5 showed some degree of eosinophilia with counts above 300 per mm.^{3}; twenty-three patients with lesions complete below T.5 were all normal.

The accompanying figure shows the mean values for plasma adrenaline, 17-ketogenic steroid excretion and circulating eosinophils in patients with complete transverse lesions of the spinal cord at levels from the fourth cervical to the fourth lumbar vertebra.

Patients with high cord lesions tend to have high eosinophil counts, low values for the plasma adrenaline and low excretions of 17-ketogenic steroids; patients with lesions of the lower thoracic and lumbar cords show normal values.

Long[4] has developed the idea that adrenaline, which is assumed to be released during stress, stimulates the secretion of adrenocorticotrophic hormone. He found that the adrenal cholesterol and ascorbic acid fell under these circumstances and also after adrenaline infusion.

Our investigations were carried out on fit subjects with spinal cord lesions of long standing who were not under stress. It is interesting that the association between the activity of the adrenal cortex, as measured by the eosinophil count and the excretion of 17-ketogenic steroids, and the output of adrenaline still appears to hold even in circumstances of subnormal adrenaline output.

Acetylcholine in Mammalian Neuromuscular Transmission

AFTER reviewing experimental results described in the literature, Acheson[1] came to the conclusion in 1948 that the amount of acetylcholine liberated by a single impulse at a presynaptic nerve terminal in muscle and sympathetic ganglia is probably of the order of $1 \cdot 5 \times 10^{-16}$ gm. (10^{-18} moles). He pointed out the large discrepancy between this quantity and the relatively large amounts (3×10^{-14} moles) hitherto found necessary for excitation when applied directly to the muscle. This discrepancy has been much reduced in recent years by the electrophoretic application of acetylcholine from micropipettes[2,7], and spikes have been produced in frog muscle fibres by this method with as little as $5 \cdot 5 \times 10^{-16}$ moles[7]. However, there still remained a substantial difference, and most of the potentials obtained by this method have not been strictly comparable with end-plate potentials elicited by nerve stimulation since they have a much slower time-course. For example, the quickest potential published by del Castillo and Katz[3] rose to its maximum in 13 msec. These authors concluded that much faster potentials, and even greater sensitivity to acetylcholine, would be expected in the case of nervous release of acetylcholine, where the diffusion distance is less than 1μ; in their

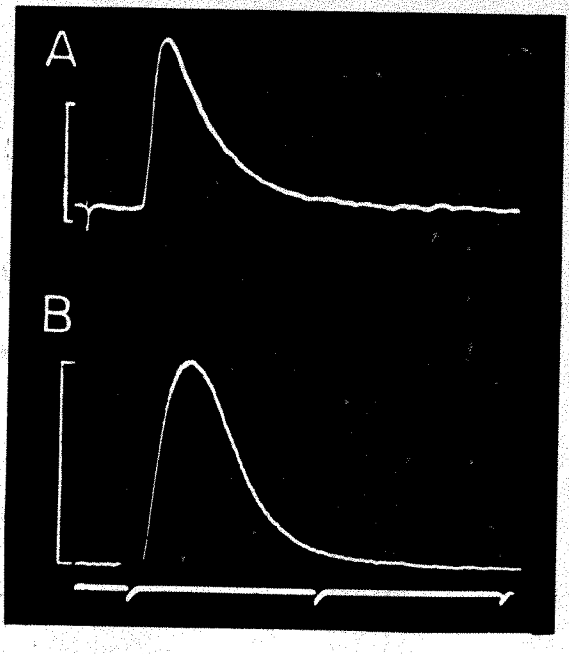

Fig. 1. *A*, End-plate potential evoked by stimulation of phrenic nerve at 2 c./s. The muscle was paralysed by 15·0 m*M* magnesium. *B*, Acetylcholine potential evoked in another muscle by a 1 msec. pulse of current ($3 \cdot 5 \times 10^{-8}$ amp.) at a rate of 1 c./s. In both cases, muscles were rat diaphragms, at 24–25° C.; the potentials were recorded with intracellular electrodes. Voltage scale: 5 mV. in *A* and 10 mV. in *B*. Common time scale: 10 msec.

experiments, the distance of the acetylcholine pipette from the end-plate was estimated to be 10–20μ (in a later paper[4], they mention potentials with a rise time of 2–5 msec.).

By the use of a similar technique, we have found that acetylcholine potentials could be produced in the rat diaphragm with amounts as small as $1 \cdot 5 \times 10^{-17}$ moles (assuming a transport number of 0·3 for ACh+). The experiments were performed *in vitro*, at room temperature (24–25° C.), with an intracellular recording electrode (filled with 3 *M* potassium chloride) in the end-plate region of a muscle fibre; jets of acetylcholine were delivered from an external micro-pipette filled with 2–4 *M* acetylcholine (as chloride, Roche Products) by square outward current pulses lasting 0·1 to 1·0 msec. The lowest values were obtained with 0·1 msec. pulses. No allowance was made for the appreciable loss of current to be expected with such short pulses in view of the relatively high pipette resistance and capacitance to earth.

The amplitude and time course of the fastest acetylcholine potentials were extraordinarily sensitive to the slightest disturbance. The fastest potentials had a time course comparable with that of end-plate potentials evoked by nerve stimulation. Fig. 1 shows on the same time scale the potential produced with a 1 msec. pulse of acetylcholine ($3 \cdot 5 \times 10^{-11}$ coulombs or 10^{-16} moles) and a typical end-plate potential in another diaphragm paralysed by 15·0 m*M* magnesium (the voltage scales differ by about 15 per cent). The rise time to the maximum of the acetylcholine potential is approximately twice as long as the corresponding time for the end-plate potential (1·3 msec.). A time lag of about 3 msec. is consistent with a diffusion distance of about 4μ. The peak of the acetylcholine potential is somewhat more rounded than that of the end-plate potential, but its rate of fall is fairly similar, so that the total durations of the two potentials differ by relatively little.

It seems that with the present technique an even closer approximation to nervous transmission is likely to be limited by the width of the end plate (19–28μ in the rat diaphragm[2]). The rounded peak of the acetylcholine potential might well be caused by saturation of the receptors closest to the pipette.

Although some discrepancy may therefore be expected to remain, the value computed somewhat indirectly by Acheson (10^{-18} moles) is quite likely to be too small by a factor of at least 10, as suggested by Acheson himself, since most experimental errors would tend to reduce it. As a further source of error, presynaptic failure of nerve conduction may well occur during repetitive stimulation[5]; it is particularly likely under conditions of reduced oxygen supply[6] such as would be expected during the perfusion of muscle with Locke solution as in the experiments reviewed by Acheson.

Metabolism of Coumarin and Related Compounds in Cultures of *Penicillium* Species

STUDIES by Mead *et al.*[1] on the metabolic fate of coumarin and related compounds in rabbits showed that *o*-coumaric acid was partly converted to 4-hydroxycoumarin while coumarin was converted neither to *o*-coumaric acid nor to 4-hydroxycoumarin.

In this laboratory the biological oxidation of coumarin and related compounds has been studied using moulds isolated from soil, following the technique of Henderson and Farmer[2]. Two of the moulds isolated, *Penicillium jenseni* and *Penicillium nigricans*, are able to utilize coumarin as sole carbon source in a modified Czapek medium, although rate of growth is very slow. During growth the concentration of coumarin falls steadily, but at no time is it possible to isolate any other coumarin derivatives. In a similar medium containing sucrose and coumarin, growth is vigorous, and a little umbelliferone is detectable.

When the medium contains *o*-coumaric acid in place of coumarin as sole carbon source, again growth rate is slow, but as the concentration of *o*-coumaric acid falls it is possible by chloroform extraction to isolate from the medium relatively large amounts of 4-hydroxycoumarin. The presence of sucrose in the medium in addition to *o*-coumaric acid does not interfere with this hydroxylation.

The isolated 4-hydroxycoumarin has been identified by its R_F values using ethylene glycol systems[3], by its mobility on paper electrophoresis in 0·2 *M* borate at *p*H 8·5, and by its ultra-violet spectrum in cyclohexane.

Paper chromatography and electrophoresis of the chloroform-soluble matter in the medium also revealed a compound with R_F values, and mobilities identical with those of dicoumarol (3 : 3-methylene-bis-4-hydroxycoumarin), but so far in too small a quantity to allow of purification for spectrophotometric comparison with pure dicoumarol. Growth of either species of *Penicillium* in a medium containing 4-hydroxycoumarin and sucrose also provided evidence for the presence of dicoumarol. In every case uninoculated control solutions showed no traces of the conversions described above.

It appears that *o*-coumaric acid, and not coumarin, may be converted to dicoumarol in cultures of *Penicillium* species isolated from soil. This is significant in view of the investigations[4] which led to the identification of dicoumarol as the hæmorrhagic agent in spoiled sweet clover hay. An early report by Smith and Brink[5] stated that alfalfa hay, containing no coumarin derivatives, developed hæmorrhagic properties when mixed with coumarin and allowed to ferment, and it has been generally supposed that coumarin is the precursor of the dicoumarol formed in fermented sweet clover hay. However, Stahmann *et al.*[4] commented on the small fraction of the total coumarin present which was apparently converted to dicoumarol. *o*-Coumaric acid is present in much lower concentrations in general, and a substantial conversion of this substance to dicoumarol by contamination of the hay with soil fungi could lead to concentrations of dicoumarol of the order of those found.

Fuller details of this work will be published in due course.

Abnormally Low Ultimate *p*H in Pig Muscle

The *p*H attained when the process of post-mortem glycolysis has ceased—the ultimate *p*H[1]—is influenced by the type of muscle considered, the species in which it occurs and the physiological condition of the animal from which it is derived. In the longissimus dorsi (l. dorsi) muscles of horses[2], oxen[3] and pigs[4], the glycogen reserves of which have not been depleted by such stresses as pre-slaughter exercise, starvation or excitement, an ultimate *p*H of about 5·5 is characteristic. At this *p*H the enzymes which effect glycolysis are assumed to be inactivated, and residual glycogen may be found. Stress, by depleting glycogen reserves at or before death, is therefore normally associated with values of ultimate *p*H above 5·5.

Some observations on pig muscles having an ultimate *p*H considerably lower than 5·5 are now briefly reported. Superficially these muscles are characterized by their loose texture, their exudative condition and, generally but not always, by the fact that they are almost white whereas normal pork is pink to light red in colour.

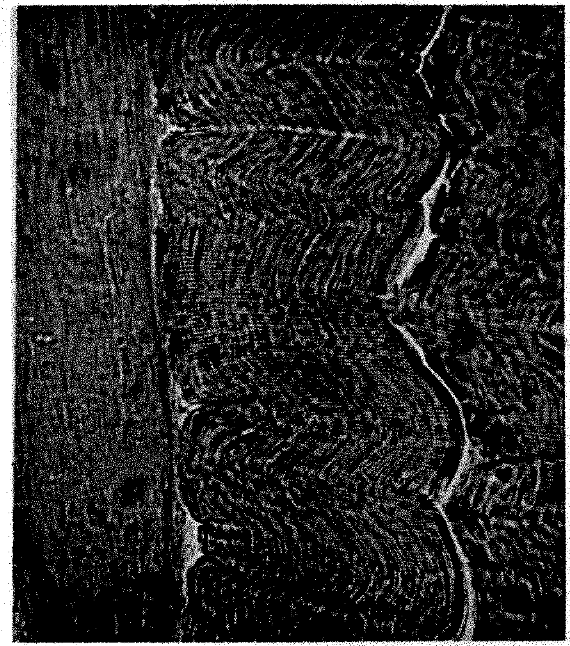

Fig. 1. Longitudinal section of pig semimembranosus muscle, *p*H 4·94. Note absence of cross-striations in left-hand fibre and twisting and corrugation of the other two. Fixed in formalin : celloidin embedded. Stained : hæmatoxylin, van Gieson. (× 200)

This 'white muscle' condition has aspects in common with "muskeldegeneration" in Danish[5] pigs and with "la myopathie exsudative dépigmentaire du porc" in France[6,7], but there are also features which appear to distinguish it from these and other distrophic disorders of muscle.

In the present work an ultimate *p*H of 5·1 or below was frequently found, the lowest value being 4·78 in l. dorsi. The latter and the semimembranosus appear to be particularly susceptible to the condition. Susceptibility also varies within a single muscle. White and pink locations in the semimembranosus only 1 cm. apart have had ultimate *p*H values of 4·94 and 5·56 respectively. In l. dorsi muscles having low *p*H there is a lower content of acid-soluble phosphorus (about 1·8 mgm./gm. compared with 2·0 mgm./gm. in l. dorsi of normal pigs) and a lower buffering power ($5{\cdot}66 \times 10^{-5}$ equivalent/*p*H/gm. compared with about $5{\cdot}9 \times 10^{-5}$ normally).

Histologically there are several unusual features, the degree of abnormality being related to the ultimate *p*H. For example, in muscles with an ultimate *p*H of 5·3, although cross-striations were still clear, the muscle fibres were frequently twisted and broken ; in those at *p*H 5·1 the protein gel in the interior of more than half of the fibres appeared to have coagulated. At *p*H 4·9 all fibres were abnormal : some of these showed no cross-striations but had manifest longitudinal markings ; others had still cross-striations but were both twisted and finely corrugated (Fig. 1). The general histological picture resembles that found in isolated muscle where *rigor mortis* has been precipitate due to an abnormally high rate of breakdown of adenosinetriphosphate (Bendall, J. R., personal communication). This aspect of the question is being studied further.

It is hoped to publish a fuller account of these investigations elsewhere.

The technical assistance of Messrs. W. A. Deer and N. King is gratefully acknowledged. Samples of

pig muscle were kindly provided by Messrs. Robert Lawson and Sons (Dyce) Ltd.

Establishment of Permanent Cell Strains from Human Adult Peripheral Blood

CULTURES of cells from the buffy coat of the blood were described by Carrel and Ebeling in 1922[1], and since then they have been used by many workers. Several have described the appearance of fibrocytic cells in these cultures[2]. They have been reported as early as one day after explantation, and Hulliger[2], using mainly rabbit buffy coat, found that within one to three weeks cultures of fibrocytic cells were frequently formed in which a high level of mitosis occurred. It would be useful to be able to establish strains of cells from individuals whenever they are required for certain genetic studies, and since the peripheral blood is the easiest tissue to obtain aseptically from volunteers, the possibility that permanent strains might be developed from this source was investigated. Strains were established from four out of five bloods. The technique used is as follows.

15–20 ml. of blood are collected in sterile siliconed tubes and buffy coat cultures are prepared in 50 ml. conical flasks, essentially by the method described by Allgöwer[2]. After one week a fluid medium consisting of 20 per cent horse or calf serum in Eagle's medium[3] (with phenol red) is added to the plasma clot cultures. About this time the cultures enter a static phase in which they remain for a period which varies from a few days to many weeks. The only evidence of the presence of surviving cells is in some cases the progressive fall in the *p*H of the medium. This is observed daily, and when it falls to 7·0 the fluid phase is renewed. Quite suddenly rapidly growing colonies of cells appear. These can be trypsinized in the usual manner and established in continuous cultivation. They resemble other 'fibroblastic' strains in morphology and grow very well in 20 per cent calf serum in Eagle's medium. They can be cloned quite easily by the dilution technique[4]. The chromosomes have been identified as human by Prof. Pontecorvo and Mr. C. G. Elliott of the Genetics Department of this University.

The origin of these cells is by no means certain. The following suggestions have been made : (1) They represent transformed monocytes or lymphocytes ; (2) they are cells carried into the vein during venepuncture ; (3) they are tissue fibroblasts or other cells, not usually listed among the leucocytes, which exist in small numbers in the peripheral blood. In view of the regularity with which they can be obtained, I feel that the second explanation is unlikely. But since their origin is at present uncertain they are best described as normal adult human buffy coat cells. We have four strains, HERT 1, HERT 2, HERT 3 and HERT 4, isolated from four different individuals and maintained in continuous culture for periods varying from six months to a year, with a minimum of thirty serial passages.

If these are normal blood elements, no matter what their precise origin, it seems that Allgöwer's suggestion that they give rise to the fibroblasts of granulation tissue has some justification. Also it seems not unlikely that many of the 'fibroblastic' strains of cells isolated from a variety of tissues may, in fact, have their origin from these blood cells. Finally, in view of the readiness with which the colonies grow from individuals the danger of using unfiltered serum in culture media is obvious.

Protoplasts of Group A Beta-hæmolytic Streptococci

THIS communication records the preparation from strains of group *A* streptococci of bodies which appear to conform to the rigid definition of 'protoplasts' recently offered by Brenner *et al.*[1]. They have been prepared by enzymic digestion of living cells.

There are two enzyme systems which attack isolated cell walls of group *A* streptococci : the *Streptomyces albus* mixture[2] and the enzyme produced during bacteriophage lysis of group *C* streptococci[3]. Both enzyme systems have been used successfully to prepare protoplasts, but the latter enzyme system is the more suitable since the streptomyces mixture contains an enzyme(s) which attacks the protoplast membrane.

Our general method has been to incubate the streptococcus (Lancefield group *A*, type 14 concentration 10^8 orgs./ml.) with the enzyme in 2 *M* sodium chloride or 2 *M* sucrose for 30 min. at 37° C. Little change in turbidity, as measured spectrophotometrically, occurs in this time and microscopical examination of air-dried stained smears of the suspension shows discrete spherical particles. Under dark-ground illumination they are indistinguishable from the original streptococcus (except possibly smaller). The suspension is centrifuged, the precipitate washed twice with 2 *M* salt solution and resuspended in a medium of suitable composition for further studies. The properties of these protoplasts, are as follows :

Osmotic sensitivity. Suspension of the protoplasts in distilled water or dilute (less than *M*) buffer brings about immediate lysis with the release of internal components of the organism. Under appropriate conditions highly viscous preparations possibly containing polymerized nucleoproteins can be prepared. Centrifugation of the lysed material at 20,000 r.p.m. for 15–30 min. gives a small pellet of insoluble opaque residue.

Immunochemistry. The protoplasts can be shown to be free of antigenic substances normally believed to occur in the cell wall. The precipitating *M* antigen and agglutinating *T* antigen, together with the group hapten, are absent when tested for by conventional typing methods. Antisera prepared against both whole and fractionated protoplasts have failed to show evidence of antibody to any of the known cell wall components.

Chemistry. Rhamnose has been shown to occur almost exclusively in the cell wall of the group *A* streptococcus. In the process of protoplast formation the rhamnose is liberated in a soluble form, which is still serologically active as group hapten. Washed protoplasts have been shown to contain less than 10 per cent of the rhamnose present in a similar sample of washed streptococci treated with inactivated enzyme. (This is a minimum figure since no account was taken of any lysis which must have occurred on washing.)

Interaction with bacteriophage. Intact cells readily adsorb appropriate bacteriophage whereas protoplasts of the same strain fail to do so.

Growth of protoplasts. Many attempts under varying conditions have been made to induce the protoplasts to grow or synthesize new cell wall material. No success has yet been attained.

Behaviour of isolated cell walls. Isolated cell walls do not appear to undergo complete dissolution when treated with partially purified enzyme preparations. Group hapten is liberated (in some cases quantitatively) but an insoluble residue remains. None of the components liberated by the partially purified enzyme appears to be dialysable.

These properties show that the enzyme treatment has removed the cell-wall components from the streptococci, and that the osmotically fragile structures produced can justifiably be called protoplasts. These protoplasts of hæmolytic streptococci are similar structures to those produced by the action of lysozyme on *B. megaterium*.

Calcium Exchanges of Ehrlich Ascites Tumour Cells of Mice *in vitro*

In a previous communication we reported the observation that when the isotope calcium-45 was injected intraperitoneally into mice bearing Ehrlich ascites tumours, the specific activity of the calcium of the cells had already reached that of the fluid after the shortest interval allowed between injection of the isotope and sampling the tumour (4 min.).

Subsequent experiments have confirmed this result, and we are now studying calcium exchange *in vitro*. In a total of six experiments in which cells labelled with calcium-45 *in vivo* were incubated *in vitro* for 10 min. at 37° C. suspended in unlabelled ascitic fluid taken previously from the same mouse, no significant exchange was found to take place between the calcium-45 of cells and fluid. The same result was obtained in five experiments in which unlabelled cells were incubated with ascitic fluid containing calcium-45. Preliminary experiments in which cells were incubated in ascitic fluid at 37° C. for up to 80 min. in the presence of calcium-45 indicate that, even for this period, exchange is so slow as to be negligible.

These results suggest that calcium exchange, which *in vivo* seemed so rapid and complete as to be plausibly explicable in terms of diffusion alone, in fact must depend on the metabolic condition of the cell.

We are at present studying the exchange of calcium by cells suspended in a nutrient, balanced medium, in the hope of imitating and investigating further the process which occurs *in vivo*.

Amœboid Motility of Fresh Ascites Tumour Cells

Using the fresh ascitic fluid of ascites tumours, and no other medium, I have studied the amœboid motility of living tumour cells. The Ehrlich ascites carcinoma and three strains of the ascites hepatoma, *AH* 130, *AH* 602 and *AH* 7974, which are transplantable ascites carcinomas of the rat established by Yoshida[1], were used. The method was as follows. A small amount of ascitic fluid was withdrawn at any time from the peritoneal cavity of host animals by means of a fine, sterile glass pipette. One drop of fresh undiluted ascitic fluid was immediately placed on the centre of a clean cover-slip, forming a globule about 5 mm. in diameter. The excess ascitic fluid was removed with the glass pipette to leave a thin flat covering of fluid. The cover-slip was then inverted over a depression slide having a depression 15 mm. in diameter and 0·5 mm. in depth, around the rim of which sufficient vaseline had been smeared to act as a seal. A slight pressure was applied to the cover-slip to seal it completely with the slide. The hanging-drop preparation was then ready for microscopic observation. The observations were carried out at 37° C. in a chamber equipped with an electric warmer.

As a rule, one hour after preparation, tumour cells of each strain became actively amœboid. In time, most of the Ehrlich ascites carcinoma cells showed amœboid movement, becoming roughly fusiform with pseudopods (Fig. 1). The ascites hepatoma is not a free-cell tumour in the strict sense of the word, as was pointed out by Yoshida[1], that is, the tumour cells, being epithelial in nature, make cell associations ('islands') suspended in the ascitic fluid, and individually isolated tumour cells are also present. In the ascites hepatoma, with the exception of *AH* 602, isolated tumour cells displayed amœboid movement, and individual tumour cells forming islands were also observed to move with pseudopods (Fig. 2). According-

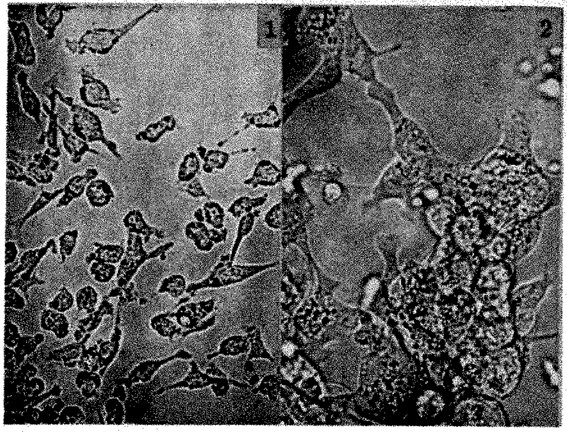

Fig. 1. Ehrlich ascites carcinoma, 6 hr. preparation. (× 135)
Fig. 2. Ascites hepatoma 130, 6 hr. after preparation. (× 270)

ing to my observations, tumour cells usually displayed amœboid movement actively for about six hours or more without showing any signs of degenerative cells. Intermingled with tumour cells, a few polymorphonuclear leucocytes, lymphocytes and macrophages were also seen. However, these could easily be distinguished from the tumour cells not only by their shape and size but even more accurately by the speed and character of their movement as reported by Enterline and Coman[2]. The alterations in positions of the estimated centre of the nucleolus of each tumour cell were traced on paper at five-minute intervals using Abbe's drawing camera. In this way, rates of amœboid movement were calculated in μ/min. (Table 1). Almost all tumour cells of *AH* 602 showed no movement with this recording technique. The average rate of movement of the Ehrlich ascites carcinoma and *AH* 7974 was 0·9 μ/min. and that of *AH* 130 was 1·0 μ/min. The difference of the average rates of movement of tumour cells among these three strains was not statistically significant. The maximum rate was calculated in μ/min. from the greatest distance any cell moved in a five-minute interval (Table 1). While tumour cells in *AH* 130 and *AH* 7974 almost always showed amœboid movement, cells in *AH* 602 did so very rarely. It is interesting that the motility should thus depend on the strain of hepatoma. Furthermore, it may be deduced that ascites tumour cells display amœboid movement in contact with the peritoneum *in vivo* too, and that they are most likely to invade in regions of the peritoneum where fluid stagnation can take place, that is, where tumour cells remain in contact with the peritoneum for some time, as Baillif[3] observed histologically, using mice inoculated with the Ehrlich ascites carcinoma.

I wish to express my sincere thanks to Prof. T. Yoshida for supplying the ascites hepatoma, and to Mr. Z. Aoki for his assistance during the course of this work.

Table 1. RATES OF AMŒBOID MOVEMENT OF EHRLICH ASCITES CARCINOMA CELLS AND ASCITES HEPATOMA CELLS

	No. of cells observed	Average rate (μ/min.) Mean ± S.E.	Maximum rate (μ/min.)
Ehrlich ascites carcinoma	19	0·9 ± 0·1	2·2
Ascites hepatoma 130	14	1·0 ± 0·1	2·2
Ascites hepatoma 7974	15	0·9 ± 0·1	2·8

Cultivation of Isolated Embryonic Rat Tibiæ on a Chemically Defined Medium

THE successful culture of embryonic chick femora and tibiæ on a chemically defined medium has recently been described[1]. The medium used was No. 858[2], which was originally designed for the culture of Earle's L-strain cells. We have now been able to cultivate embryonic rat tibiæ on a closely related, chemically defined medium (J. D. Biggers and J. A. Lucy, unpublished work), thus paving the way for future studies on the specific nutritional requirements and metabolism of growing mammalian cartilage.

The bones have been cultured by means of the floating-lens paper technique devised by Chen[3]. Each watch-glass contained 0·5 ml. of medium and this was used for the cultivation of one tibia, the medium being renewed every second day. Rat fœtuses of a known age were obtained from the Medical Research Council strain of albino rats bred in the Department. The occurrence of mating was determined by finding a vaginal plug, the day on which the plug was found being counted as the first day of pregnancy. On the seventeenth day of pregnancy the uterus and conceptuses were excised. The fœtuses were immediately freed from their fœtal membranes and placed in fresh sterile Tyrode's solution at room temperature until the tibiæ could be isolated. In previous experiments it was found that the growth of the tibiæ was poor when the bones were isolated from fœtuses which had remained in the isolated uterus. The tibiæ were removed under a dissecting microscope and cleaned of as much extraneous tissue as possible, leaving the perichondrium intact.

Tibiæ from 17-day-old rat fœtuses may vary between approximately 1 and 3 mm. in length. This variation is mainly between pregnant rats, and may be accounted for largely in terms of the variation between individual rats in the number of embryos *in utero*. The shorter bones are composed of hyaline cartilage with intact hypertrophic cells in the centre of the diaphysis. The longer bones possess, in addition, a narrow collar of ossification in the diaphysis and, further, the central hypertrophic cells may have started to degenerate as a preliminary to endochondral ossification.

Pilot experiments showed that 17-day-old embryonic rat tibiæ elongate when they are cultivated on the chemically defined medium. Since previous work with embryonic chick long bones demonstrated that the degree to which bones elongate depends considerably on the level of glucose which is originally present in the medium[1,4] an experiment was designed to examine the effect of glucose on the elongation of rat tibiæ. Six batches of media were prepared, containing 0·5, 1, 2, 4, 8 and 16 mgm./ml. glucose respectively. These glucose levels form a set of six treatments which

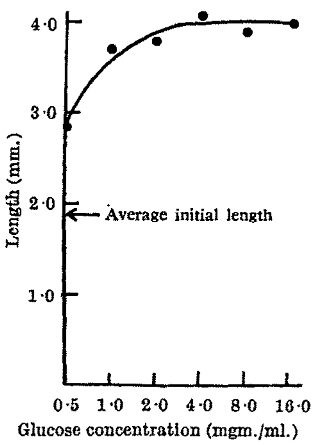

Fig. 1. The effect of glucose concentration on the length of 17-day-old embryonic rat tibiæ cultivated for five days on a chemically defined medium. Each point is the mean of six observations

were replicated six times in a randomized block design. Three pregnant rats were used, each providing the tibiæ for two blocks, and the tibiæ forming each block were allocated to the six treatments by means of a table of random numbers. Thus the comparison of the glucose levels is made within pregnant rats with a considerable gain in precision. The bones were drawn daily by means of a camera lucida, and the lengths of the bones at different stages were calculated from these drawings. Standard statistical methods were used to analyse this experiment. The results were transformed to the logarithmic scale before analysis.

The effect of concentration of glucose on the length of the bones after 5 days cultivation is shown in Fig. 1. The dose-response line was calculated after allowing for variations in initial length by an analysis of covariance. The results show that a glucose-level of less than 3 mgm./ml. is insufficient to promote maximum elongation. With higher glucose-levels the dose-response line becomes horizontal, indicating that glucose has no deleterious effects in concentrations up to 16 mgm./ml. This finding suggests that, as in the case of embryonic chick tibiæ, glucose penetrates the cells so quickly that the osmotic action of high concentrations is transitory, with no permanent effects on the subsequent growth of the bones. The elongation observed when the concentration of glucose in the medium is greater than 3 mgm./ml. was 112 per cent. Fig. 2 shows the type of growth which is obtained under these conditions. In some specimens the morphology remains approximately normal, and in others, curvature of the diaphysis may develop.

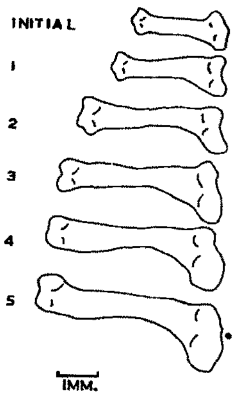

Fig. 2. Daily camera lucida drawings of a 17-day-old embryonic rat tibia cultivated on chemically defined medium (glucose concentration, 4 mgm./ml.). The medium was renewed on the second and fourth days

A second experiment was carried out to examine the histology of embryonic rat tibiæ grown on a chemically defined medium, containing 4 mgm./ml. glucose. Twenty tibiæ were explanted and at daily intervals four of these were chosen at random and fixed in Zenker containing 3 per cent acetic acid. Sections of these bones were stained with Ehrlich's hæmatoxylin and erythrosin and also with Heidenhain's hæmatoxylin. The bones remained healthy up to 4 days. The cells of the epiphysis and diaphysis retained their normal morphology, and the nuclei of these cells often contained two or three clearly defined nucleoli. Mitoses were easily found in the cells of the epiphysis up to the third day. At five days some of the hypertrophic cells of the diaphysis were degenerate, although the epiphyseal cells were still normal.

We have also attempted to culture 18-day embryonic mouse tibiæ on a chemically defined medium. The elongation which was obtained was of a similar magnitude to that recorded by Fell and Mellanby[5] using a natural medium. The elongation, however, was relatively small in comparison with that obtained with 17-day rat tibiæ. The difference in growth in the two cases is probably related to the difference in the initial structure in the tibiæ when they are explanted. In the rat, very little or no ossification of the diaphysis has occurred, and elongation is caused by hypertrophy of the diaphyseal cells, proliferation of the epiphyseal cells and secretion of new matrix. At this stage hypertrophy of the diaphyseal cells plays a major role in the elongation of the tibiæ which occurs *in vivo*[6]. In the mouse, on the other hand, there is considerable ossification of the diaphysis so that elongation cannot result from hypertrophy of diaphyseal cells, but largely depends on the proliferation of epiphyseal cells and the secretion of matrix between them. It would be interesting to explant mouse tibiæ at a stage of development comparable with that of 17-day-old embryonic rat tibiæ but, unfortunately, this has not been possible for technical reasons.

We wish to thank Mr. John Roberts for skilled technical assistance. Also we wish to acknowledge generous grants from the Royal Society, the Nuffield Foundation, the Medical Research Council and the Central Research Fund of the University of London, which made this work possible.

Pigments Present in Arms and Pinnules of the Crinoid, *Antedon bifida* (Pennant)

In *A. bifida* red pigment usually occurs in protein granules in superficial connective tissue and in the eggs. The skeleton is colourless. When freshly detached pinnules are placed on slides and covered with sodium hydrosulphite solution, microscopic examination reveals that the red colour is immediately lost, but is restored in the granules when this solution is replaced quickly by sea water, and more markedly if drops of hydrogen peroxide are added to the sea water. Cannan[1] applied this test to *Arbacia* and *Echinus* echinochrome with similar results. The pigment restored in colour passes gradually into the protein pyriform bodies in the sacculi in *Antedon*. In distilled water the red pigment also passes into these bodies, which are discharged. Ball[2] used acid alcohol to extract echinochrome from *Arbacia*, and this solvent proved to be effective in removing selectively the red pigment from *Antedon* from Plymouth. Extraction procedure and tests performed were as follows:

1. Living arms and pinnules of 10 animals were cut up into 50 ml. of acid alcohol (70 per cent methyl alcohol containing 0·75 per cent conc. hydrochloric acid). Pigment extracted was placed in a separating funnel.
2. 50 ml. of petroleum ether and later 60 ml. of distilled water were added to the extract, which was shaken so that carotenoids and lipids might pass into the epiphase.
3. The hypophase containing the red pigment was run into a further separating funnel. About 20 ml. of distilled water of *p*H 5 (from a metal still) and 50 ml. of diethyl ether were added. The red pigment passed into the epiphase. If 20 ml. of glass distilled water is used instead, the red pigment remains in the hypophase, but on addition of a little hydrochloric or acetic acid it rises into the ether. In this instability the pigment resembles the hydroxy-naphthaquinone extracted by Ball and Cooper[3] from *Arbacia*, and by Millott[4,5] from *Diadema antillarum*; furthermore it is orange in aqueous acid solution and deep red in alkaline. A green colour, indicative of a phenol, appears if ferric chloride solution is added to a sample of this pigment in distilled water acidified with hydrochloric acid.
4. Samples of the ethereal solution of pigment dried with anhydrous sodium sulphate were examined in a Beckman spectrophotometer.

Absorption peaks occur at 262 mμ, 337 mμ, 460 mμ and there is an inflexion at 510 mμ—all as in the naphthaquinone pigment from *Diadema*[4,5] except that the maxima at 337 and 460 mμ are less well marked.

Yellow-brown lipid granules (which take up sudan dyes) are present in deposits in connective tissue and in coelomocytes. The brown colour is not removed by changes of acetone or ethylene chlorohydrin. In sections these granules blacken with alkaline silver methenamine. Since 0·13 per cent *l*-tyrosine is blackened slowly by ground arms and pinnules, some tyrosinase is possibly present in them, but use of the Hueck and Long Ziehl–Neelsen tests (see Pearse[6]) indicate that the yellow-brown material contains lipofuscin (oxidized lipid), not melanin, and bleaching tests bear this out, for very little brown colour is removed when sections 7μ thick are placed in 30 vol. hydrogen peroxide or 1 per cent bromine water for 48 hr.

Carotenoid pigments are present in gut wall and gonad, but can be extracted from the region of the arm-tip, which contains practically no gonad. I am indebted to Dr. L. R. Fisher for identification (using the methods of Fisher, Kon and Thompson[7]) of β-carotene, esterified astaxanthin (peak at 465 mμ in *n*-hexane), astaxanthin and xanthophyll (peak at 445–447 mμ in *n*-hexane) in extracts of arms and pinnules of *A. bifida*. Echinenone and vitamin A appeared to be absent. In its arms *A. bifida* seems to have several carotenoid pigments which resemble those found in the integument of starfish such as *Marthasterias glacialis*[8]. The carotenoids, α-carotene, β-carotene, echinenone, esterified astaxanthin and xanthophyll have been found in echinoderms and the occurrence of some of these pigments in the crinoid *A. bifida* might be expected.

Certain pigments present may be of dietary origin. *A. bifida* is both a detritus and suspension feeder. Small copepods are ingested with detritus. Diatoms are digested.

Like the echinoid *Diadema*[9], this crinoid responds to light. Animals so placed that aboral cirri rest on the bottoms of bowls will stay still in very dim light for half an hour, but rise up and swim when exposed to 160 ft. candles of light from an electric bulb for 4 sec. Preliminary work indicates that this response is also given when green, but not when blue, yellow or red filters are placed in front of the light; a light-sensitive pigment may be present in the nervous system.

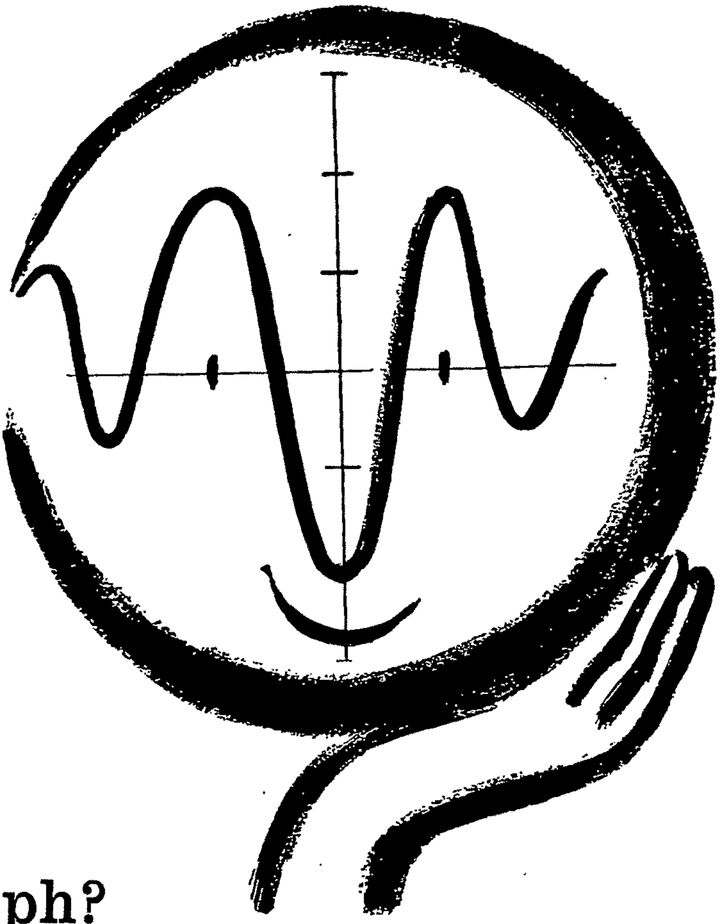
The Finer Structure of the Galeal Lamella in Adult Mosquitoes

The maxilla of the adult mosquito is a reduced structure in that the cardo and lacinia are almost lost, and the stipes is embedded below the alimentary canal. The functional maxilla is a lancet-like galea consisting of a chitinized rod with a trough-shaped membranous lamella on its outer edge. This lamella has been described in *Anopheles maculipennis* as possessing fine anastomosing striations and bearing at its distal extremity small, backwardly pointing teeth[1]. The piercing action of the maxillary galea has been described elsewhere[2].

Studies being carried out upon the detailed structure of the trophi of adult Culicidae have revealed that in many species the lamella has a more complex structure than previously believed. In *Aedes argenteoventralis*, *Culex horridus*, *C. cinereus* and *C. fatigans*, a very fine non-striated lamella on the inner side of the galea has been observed. The structure of the outer lamella has particularly been studied in *Aedes aegypti*, *A. grahami*, *Culex nebulosus*, *C. cinerellus*, *C. fatigans*, *Uranotaenia bilineata* and *Hodgesia*



Thinking about an oscillograph?

If you are experienced in the design of high quality instruments, our Technical Director would be glad to hear from you.

FOR USE IN ELECTRONICS? From the wide range of single and double-beam instruments, a model is available to suit the requirements of all sections of this expanding industry.

IN INDUSTRY? Diverse industries are finding solutions to their design and production difficulties with the aid of the Cathode Ray Oscillograph. Our Technical Advisory Service will be pleased to help you with your specific problem.

IN SPECIALISED FIELDS? Unusual types of oscillograph have been designed for specialised applications in the Hydraulic, Marine and Ultrasonic fields. We shall be pleased to consider specific development projects.

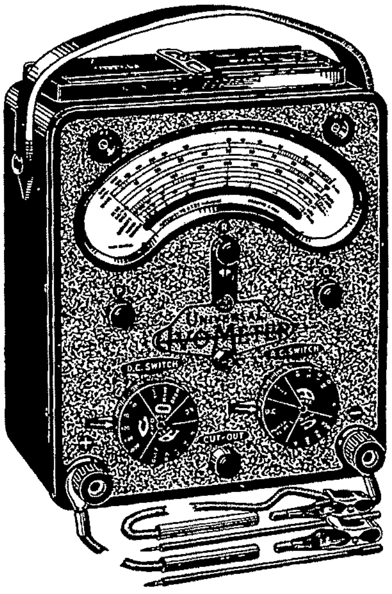
Instrumentally Speaking

Wherever electricity is used in industry, there is a need for electrical measuring instruments. Phenomenal development in the war and post-war years has produced a need for such a multiplicity of instruments of different kinds that there is a prevailing tendency towards the slowing down of maintenance and laboratory work through having too many instruments in use. Incidentally, too much test gear also means too much expense. The answer to such problems is provided by "Avo" MULTI-RANGE instruments.



The Model 7 Universal AvoMeter is a typical example of a modern "AVO" multi-range meter. It is a combination A.C./D.C. instrument providing on a 5-inch hand calibrated scale 50 ranges of readings of Current, Voltage, Resistance, Capacitance, Power Output and Decibels. The total resistance of the instrument is 500,000 ohms, and its small power consumption and precision accuracy make it the choice of radio, television and electrical engineers throughout the world. An external accessory is also available for measuring Power and Power Factor.

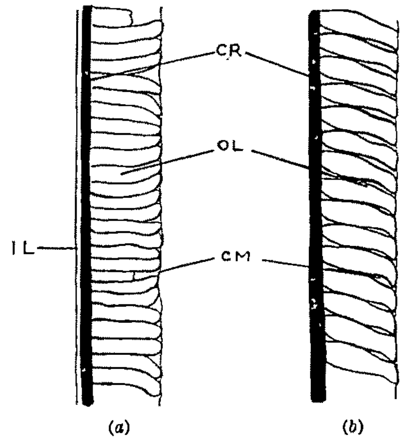

Fig. 1. Sections of the maxillary galeæ in (*a*) *Culex fatigans* and (*b*) *Aedes grahami*. *OL*, Outer lamella; *IL*, Inner lamella; *CR*, chitinized rod; *CM*, connecting membrane

nigeriae. In these species the lamella has the appearance of being composed of a great number of finger-like projections arising from the chitinized rod, which are separate at their distal extremities (Fig. 1). Normal pressure on a coverslip over the portion of the lamella under observation does not cause separtion of the individual parts, but when the lamella is broken these can be observed. Although these projections are considered to be separate entities, it has been observed that they are connected to one another by a much finer continuous membrane. Examination of longitudinal sections of the proboscis reveals that these projections are indeed separable when the galea is cut at an oblique angle while still in the labial sheath.

The structure of the lamella as described here has been observed in a number of widely separate species, and it is doubtful whether this type of structure is related to a particular feeding habit. Nevertheless, the possession of a lamella with a serrated, or semi-serrated, edge would be of value to a species which is a blood feeder and must therefore be able to pierce animal tissue.

Dependence of Mitochondrial Swelling on Oxidizable Substrates

That the swelling of isolated mitochondria induced by various agents fails to occur under anaerobic conditions[1,2] suggested to us that swelling may be dependent on respiration. The probability of this is increased by the finding[3,4] that malonate prevents the swelling induced by succinate of mitochondria suspended in mannitol or sucrose solutions. We have therefore studied the effects of addition of substrates and inhibitors of oxidative metabolism on the swelling of mitochondria under various conditions. Mitochondria from livers of male rats (180–280 gm. body-weight) were prepared, suspended and stored in 0·44 *M* sucrose at 0° C. 0·05 ml. of mitochondrial suspension (25 mgm.-equivalents; 0·1 mgm. nitrogen) was added to 2·95 ml. of medium containing 2-amino-2-hydroxymethylpropane-1 : 3-diol (*tris*) chloride buffer, *p*H 7·5, and sucrose (final concentrations 25 m*M* and 0·3 *M* respectively). The optical density at 520 mμ (D_{520}) was recorded for periods up to 1 hr., the temperature being thermostatically controlled at 20°. Decreases in D_{520} were taken as a measure of swelling. Substrates were used in 1 m*M* concentration.

In contrast to the experience of previous workers[2,4], negligible swelling occurred during 1 hr. incubation in standard medium containing no further additions, even at 25° C. or after storage of the mitochondria at 0° C. for 26 hr.

With fresh mitochondria, the swelling caused by phosphate (10 m*M*) was increased in extent by addition of D-β-hydroxybutyrate, succinate, L-glutamate, L-malate or L-proline. These substrates, in absence of phosphate, produced negligible swelling. The effect of phosphate alone decreased as the age of the mitochondria increased. It was negligible after 18 hr., and was then restored by addition of the above substrates, which again had no effect when added alone. Pyruvate and α-oxoglutarate were, however, ineffective under these conditions.

The swelling of day-old mitochondria in the presence of succinate and phosphate ('succinate – phosphate swelling') was inhibited by malonate (1 m*M*) (Fig. 1), whereas the D-β-hydroxybutyrate – phosphate and L-glutamate – phosphate swelling was not. 1·8 m*M* amytal (5-ethyl-5-*iso*amylbarbiturate) prevents the oxidation by mitochondria of substrates

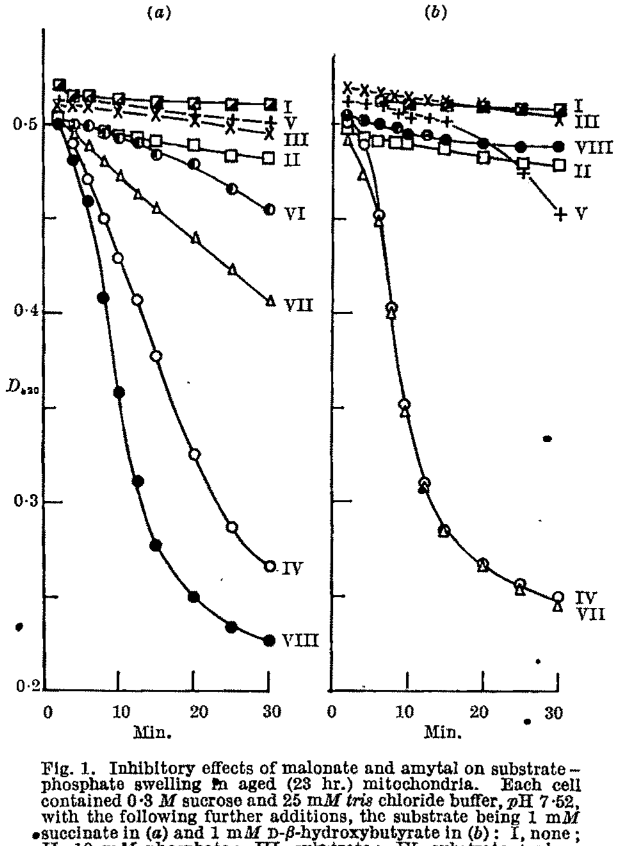

Fig. 1. Inhibitory effects of malonate and amytal on substrate – phosphate swelling in aged (23 hr.) mitochondria. Each cell contained 0·3 *M* sucrose and 25 m*M* *tris* chloride buffer, *p*H 7·52, with the following further additions, the substrate being 1 m*M* succinate in (*a*) and 1 m*M* D-*β*-hydroxybutyrate in (*b*): I, none; II, 10 m*M* phosphate; III, substrate; IV, substrate + phosphate; V, substrate + 1 m*M* malonate; VI, substrate (succinate only) + 2 m*M* amytal; VII, substrate + phosphate + malonate; VIII, substrate + phosphate + amytal

with diphosphopyridine nucleotide-linked dehydrogenases, but has no effect on the oxidation of succinate[5]. It is therefore of interest that 1·8 or 2 m*M* amytal inhibited the swelling caused by D-β-hydroxybutyrate, L-glutamate, L-malate or L-proline when added together with phosphate, but not the succinate – phosphate swelling (Fig. 1). Antimycin *A* (0·05 μgm./ml.), which blocks the respiratory chain[6], inhibited by 50–100 per cent the swelling induced by all the above substrates, including succinate, in presence of phosphate. Cyanide (1 m*M*) abolished the D-β-hydroxybutyrate – phosphate swelling of fresh and aged mitochondria.

Studies of the swelling induced by thyroxine have provided similar evidence that swelling may be dependent on the presence of oxidizable substrates. Thus, with fresh mitochondria, D-β-hydroxybutyrate enhanced, and with aged mitochondria restored, the thyroxine effect. D-β-Hydroxybutyrate – thyroxine swelling was inhibited by amytal and antimycin *A*. Still further evidence has been provided by the observation that with day-old particles in 0·2 *M* sucrose buffered with 25 m*M* *tris*, swelling was induced by succinate, D-β-hydroxybutyrate and L-glutamate. Malonate strongly inhibited the effect of succinate but accelerated that of the other two substrates.

With fresh mitochondria, replacing the *tris* buffer by glyoxaline or raising the sucrose concentration from 0·3 *M* to 0·5 *M* prevented swelling due to phosphate. This could then be restored by addition of D-β-hydroxybutyrate but not of L-glutamate, L-proline or succinate. With 0·45 *M* sucrose, however, L-proline and succinate were effective. In this connexion the recent finding[7] that high concentrations of sucrose inhibit the oxidation of different substrates in different degrees may be significant.

To summarize, under various conditions addition of certain oxidizable substrates promotes swelling. The effect of these substrates is diminished by substances known to inhibit their oxidation. We therefore suggest that in certain circumstances the swelling of mitochondria is dependent on their respiration. Since cyanide, amytal and high concentrations of sucrose inhibit the swelling of fresh mitochondria in the presence of phosphate or thyroxine, it may be that such swelling is supported by the oxidation of intrinsic substrates. Ageing might deplete the particles of substrates, and swelling then only occur if these are supplied. The stabilizing action of 2 : 4-dinitrophenol[4], which we have observed under many conditions, indicates that any effect of respiration on swelling may be exerted through coupled phosphorylation.

We thank Mr. Colin Taylor for his technical assistance.

Effect of Low Temperature on the Vertical Distribution of Two Wood-boring Crustaceans

WHEREAS normal marine animals may be subjected to a temperature of not less than the freezing point of sea water, animals inhabiting the inter-tidal zone sometimes experience a much lower temperature. This is particularly so in the high-latitude shores of Norway where, during the winter, an inter-tidal zone of 3·5 m. is exposed twice daily to as low a temperature as −20° C. for 6 hr. or more. While studying the distribution of marine wood-borers in the Norwegian coasts, the possible stress of low temperature on these organisms came under consideration. Kanwisher[1] found some inter-tidal animals able to survive with as much as 75 per cent of their body fluids converted as ice. In *Limnoria*, Sømme[2] found that 83 per cent died when frozen in ice for 2·5 hr. With the view of finding out the extent of tolerance and any evidence of an adaptability to sudden drops in temperature which these animals experience when they are exposed to the air by the receding tide, the following experiments were performed.

Sectors approximately 50 cm. × 15 cm. × 5 cm. in size infected by borers obtained from nearby piles, were used in the experiments. These were acclimatized in a submerged condition from +6° C., the temperature of the surrounding water, to +2° C. during the course of 24 hr., after which they were exposed to air of different low temperatures in thermostatically controlled chambers where the variation during the course of any experiment was not more than ±2° C. After definite intervals of time, approximately 25 cm.^{2} of the superficial part of a block, with its contained animals, was sawn out and transferred to sea water at +2° C. where it was left for 12 hr. for recovery from exposure. After this treatment, the piece of wood was carefully dissected and the animals in it released into fresh sea water and watched for signs of life under a binocular microscope. Those that showed no signs of movement even after gentle teasing were counted as dead. Several series were run, each involving more than 500 animals, in order to allow for individual variation.

In these experiments an effort has been made to reproduce so far as possible the actual conditions experienced by these animals in Nature, thereby avoiding the artificial conditions of earlier observations (ref. 2, p. 153 and ref. 3) where animals were removed from their burrows, kept in water and subjected to low temperatures. However, the present procedure introduces an uncertainty regarding the actual temperature experienced by the animal in the burrow. Therefore, to give an idea of the rate of cooling of the log, a test run at −6° C. was carried out which showed that, at a depth of 2 cm., which is approximately the level to which *Limnoria* penetrates, the ambient temperature was reached within 3 hr. The results of the experiments are shown graphically in Fig. 1.

The three experimental periods presented in the graph represent three different exposure-periods to which *Limnoria lignorum* (Rathke) and *Chelura terebrans* (Philippi), occupying different positions on a pile in the inter-tidal zone, experience during the recession of the tide. Assuming 50 per cent mortality as a limit of tolerance of the population under consideration, it will be seen that a temperature of −4° C. is of no serious effect on *Limnoria*. On the

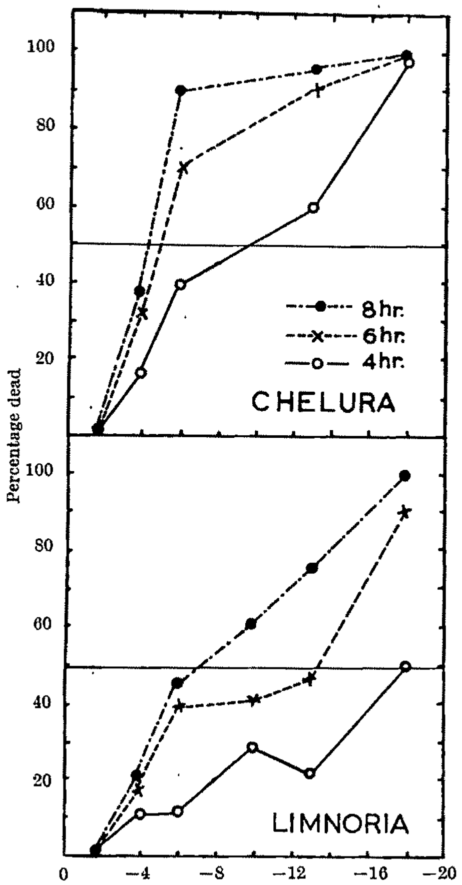

Fig. 1. Curves illustrating the death of *Chelura* and *Limnoria*, in sectors of logs exposed to different temperatures for various exposure times

other hand, this limit is almost reached within 8 hr. for the amphipod borer. This means that only those inhabiting the higher levels above mid-water mark will be affected by this temperature. Exposure to −8° C. for a period of 8 hr. kills 50 per cent of *Limnoria*, whereas this point is nearly reached within 4 hr. for *Chelura*. The latter temperature would therefore be a serious stress on those *Chelura* living both above and below the mid-water level. For a majority of *Limnoria* living at higher levels above the low-water mark a temperature of −18° C. is detrimental, since an exposure of only 4 hr. is sufficient to kill 50 per cent.

It may be inferred, therefore, that a sudden drop of temperature to −20° C. is lethal for those animals living high up on the piles above the low-water mark. Furthermore, the whole population of the inter-tidal belt experiences the great stress of low temperature during the period of exposure. It is doubtful that an organism which is subjected to such a stress under the conditions stated will continue to live and reproduce in an environment with this stress imposed rhythmically twice a day. The only escape to better conditions is by active migration to more favourable locations. It was interesting to note during the experiments that many of these animals when thawed out from a state of suspended animation showed a tendency to swim out of their burrows, suggesting that they are capable of migration. Evidently, as they emerge from their dark burrows they are influenced by photic stimuli. Since the degree of settlement has been reported as inversely proportional to increasing intensity of light[4], they move to lower levels in the same pile or adjacent piles. This would explain why empty burrows are found on piles above the low-water level after the winter months. It is noteworthy that during February, which is normally the coldest month in these localities, a secondary migration of *Limnoria* has been recorded (ref. 2, p. 202) besides the primary one, which takes place during September–October. It is not improbable that some of these February migrants are from the inter-tidal zone and have deserted it in search of a more favourable habitat.

This, then, may also explain the reported peculiarity in the vertical distribution of these borers in northern latitudes, where sub-zero atmospheric temperature is quite a normal feature during the greater part of winter. Those individuals that ascend too high up the pile would be killed, establishing an upper limit in the distribution. This limit may later be extended as re-colonization is made possible on the return of more favourable conditions and when population pressure drives individuals to unoccupied regions on the pile. The progressive decrease in the infestation of *Limnoria* from the mud-line upwards in these localities, in contrast to the condition reported from several places in the south (ref. 2, p. 151), support this view.

Trisaccharides of *Lolium* and *Festuca*

In the course of an investigation into the distribution of water-soluble carbohydrates in seeds of the Gramineae[1], it was observed that two species of grass (*Lolium perenne* L. and *Festuca pratensis* Huds.) contained in their caryopses substantial amounts of a trisaccharide which was not detected in any of the thirty other wild grasses and cereals examined. This non-reducing trisaccharide (Fig. 1, X) had a specific rotation of +90·5° (without recrystallization), yielded equal amounts of galactose, glucose and fructose on acid hydrolysis and was readily broken down to fructose and a reducing disaccharide in the presence of invertase or very dilute acid. This ease of hydrolysis suggests that the trisaccharide resembles raffinose in containing a terminal β-fructofuranoside residue. Iodine oxidation[2] indicated that the galactose residue was at the non-reducing end of the disaccharide, and electrophoretic mobility of the disaccharide in borate was intermediate between the mobilities of laminaribiose and melibiose. Movement in borate is allied to the mode of linkage of sugar residues[3], disaccharides containing 1,2 or 1,4 linkages being of much lower mobility than those containing 1,3 or 1,6 linkages. The disaccharide under consideration would therefore appear to contain either a 1,3 or a 1,6 linkage. Although the electrophoretic behaviour in borate does not distinguish between α and β linkages, the high positive rotation of the trisaccharide suggests

Table 1. OLIGOSACCHARIDES OF *Lolium* AND *Festuca*

	Sucrose	Raffinose	Other trisaccharide	Tetrasaccharide
Lolium perenne	+	–	+	–
L. italicum	+	–	+	–
L. temulentum	+	–	+	–
Festuca pratensis	+	–	+	–
F. arundinacea	+	–	+	–
F. rubra	+	+	+	+
F. ovina				
Ssp. *ovina*	+	+	+	+
Ssp. *tenuifolia*	+	+	+	+

+, Present; –, not detected.

that the galactose and glucose residues are α-linked, and, since 6-glucose-α-galactoside is melibiose, it seems probable that the newly isolated disaccharide is 3-glucose-α-galactoside. The trisaccharide from *Lolium perenne* and *Festuca pratensis* is therefore tentatively described as α-D-galactopyranosyl-3-α-D-glucopyranosyl-2-β-D-fructofuranoside.

The presence of this rather unusual trisaccharide in two members of the Festuceae and its apparent absence from certain other members of the tribe (*Dactylis* and *Cynosurus*)[1] raises the interesting possibility of examining the biochemical affinities of different species of *Festuca* and *Lolium*. It will be recalled that recent morphological and genetical studies of these two genera have cast doubts on their traditional taxonomic alignment. Tutin[4], for example, concludes that *L. perenne* should be transferred to *Festuca*, while Stebbins[5], considering that *F. pratensis* is more closely related to *L. perenne* than it is to other species of *Festuca* such as the type species, *F. ovina*, regards the 'genus' *Lolium* as a section of the large and diverse genus *Festuca*.

The results of chromatographic analyses of the sugars of several species of *Lolium* and *Festuca* are shown in Table 1 and in Fig. 1. All species examined contained the trisaccharide described above, and all three species of *Lolium* gave chromatograms identical with those of *F. pratensis* and *F. arundinacea*. *F. rubra* and *F. ovina*, however, contained two other non-reducing oligosaccharides, both of which yielded galactose, glucose and fructose on hydrolysis. The more mobile of the two was chromatographically identical with raffinose; the other, which was probably a tetrasaccharide, was not chromatographically referable to stachyose, and calculation of the expression[6] log $[R_F/(1 - R_F)]$ indicated that it might be a higher homologue of the *Lolium* trisaccharide.

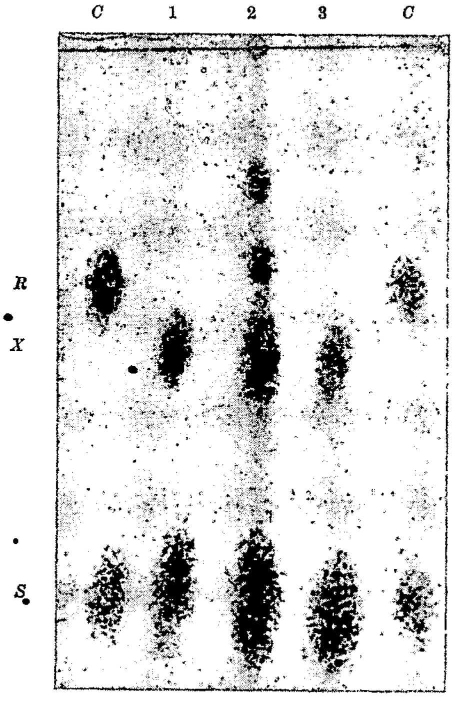

Fig. 1. Oligosaccharides of *Lolium* and *Festuca*. *C*, Control sugars; *R*, raffinose; *S*, sucrose. 1, *Lolium perenne*; 2, *Festuca rubra*; 3, *Festuca pratensis*; *X*, trisaccharide (see text). Solvent: *n*-propanol/water, 78/22

The presence of the same rather unusual trisaccharide in all species of *Lolium* and *Festuca* examined is further confirmation from a somewhat unexpected source of the close relationship of the two genera. Moreover, as far as the distribution of sugars is concerned, the affinities of *Lolium* lie with *F. pratensis* and its allies rather than with *F. ovina*, which has a more complicated pattern of oligosaccharide distribution.

We wish to express our thanks to Dr. Mary Noble, Plant Pathology Station, East Craigs, Edinburgh, for a supply of *Lolium temulentum* and to Mr. L. S. Cobley, Edinburgh and East of Scotland College of Agriculture, for samples of *Festuca*.

Populations of *Agrostis* spp. Tolerant of Heavy Metals

A NUMBER of collections of *Agrostis tenuis* and *A. stolonifera* have been obtained from sites contaminated by heavy metals. Some of these have been tested for tolerance of four metals, copper, nickel, zinc and lead, using as controls populations from more normal habitats. The method used in testing is derived from that of Wilkins[1]. The amount of root growth in solutions containing the heavy metals is expressed as a percentage of that in solutions containing none. All culture solutions contained 1 gm./l. hydrated calcium nitrate. The copper and lead were present as nitrates, the zinc and nickel as sulphates. The results are shown in Table 1, each figure being a mean value for 20 plants in two replicates.

The populations are numbered 1–8 as follows: 1, A population of *A. alba* (identified as *A. stolonifera* L.) from a site at Piésky, Slovakia, described by Prát[2] as soil enriched in copper by a stream flowing from an old copper mine (provided by Prof. Fott and Dr. Jan Futák). 2, Population *D* of *A. stolonifera* from Port Meadow, Oxfordshire[3]. 3, *A. tenuis* from a copper-poisoned soil in an old mining area near Parys Mountain, Anglesey. 4, *A. tenuis* grown from seed provided by Dr. W. Krause, and described by him as being from the 'poison spot' of an old nickel mine in the Black Forest. 5, *A. tenuis* also provided by Dr. Krause, seed obtained from normal heath and

Table 1. ROOT GROWTH IN TOXIC SOLUTION AS A PERCENTAGE OF NORMAL GROWTH

Concentration (micromoles/l.)		Population

	10	9	2	11	84	18	43	19	9
	15	4	0	3	70	4	14	10	0
Pb	75	26	18	37	27	16	22	80	28
	125	17	9	20	22	10	18	62	12
Zn	20	37	38	61	65	35	54	54	34
	40	21	17	33	42	19	38	48	21
	60	8	4	24	23	10	27	30	13

near the mine. 6, *A. tenuis* from a mine spoil-heap in North Wales, at first thought to contain lead, but now known to contain no significant amount of lead, but some zinc and possibly other metals. 7, *A. tenuis* from Goginan mine, Cardiganshire, previously described as resistant by Bradshaw[4]. The soil contains lead and zinc in toxic amounts. 8, *A. tenuis* from a meadow near Capel Bangor, Cardiganshire.

Each population except 2, 5 and 8, which were the controls, shows a marked degree of resistance to poisoning by the metals known to be present on the sites from which they were collected. The rather high degree of tolerance shown by the control 5 to nickel may be due to it having been grown in the same container as 4, which may have been removing a significant amount of nickel from the solution. However, without information as to how close to the mine the seed was taken, the possibility of some gene-flow from the nickel-resistant population cannot be eliminated.

A lesser degree of tolerance is also shown, in general, to other metals not known to be present. In the absence of detailed soil analyses, which are proceeding, the presence of other metals in the soil is possible, but it is suggested that the tolerance shown is due to an extension of the resistance mechanism operative against the main toxic agent. Population 6 is rather a special case, but seems to show its main resistance to nickel, although this is not so marked as in the Black Forest population.

On these sites the plant cover is generally very poor, especially where the calcium content is low, and very few species can cope with such an extreme environment. It is notable that two closely related species have proved capable of adapting themselves to meet these conditions with respect to a number of metals in several localities during the short time in which the sites have been available. The necessary genetic variation seems to be present in the genus *Agrostis* throughout a large part of its range.

The order of toxicity shown is copper > nickel > zinc > lead, which agrees with that given by Hewitt[5] and De Kock[6] for a range of plants, and also follows the Mellor–Malley series[7] for the order of stability of metallic-organic complexes. Furthermore, there are indications that the greater the degree of toxicity the more clear cut is the tolerance of it, excluding zinc, where no highly resistant population has yet been found. This lends support to the hypothesis that the resistance is due to the metal ions being bound internally by a process analogous to chelation; such a process would be most effective where the chelates are most stable. This would also explain the high concentrations of toxic metals in plants from poisonous sites noted by various authors[8,9].

However, unlike chelation the process is fairly specific for individual metals. Where activity is shown against lead, a lesser activity is shown against copper; not a higher as would be expected from the series quoted above. The advantage of this to the plant is apparent, in that it does not have micronutrient ions, which may not be abundant, made unavailable internally. If the plants have succeeded in elaborating a series of compounds capable of specific chelation, further study may be rewarding.

Fleas of the Rat in Tanganyika

THE flea records presented here have been based on a two-year study of *Rattus rattus* (L.), the commensal rodent of Tanganyika. No previous list of the flea fauna of *R. rattus* of Tanganyika is known. In all 1,788 specimens of *R. rattus* were obtained and their fleas collected.

The term *Rattus rattus* (L.) used here is one of convenience and embraces the very mixed, interbred population formed of strains of *R. r. rattus*, *R. r. frugivorus*, *R. r. alexandrinus* and *R. r. wroughtoni*, that is peculiar to Tanganyika and perhaps to other parts of East Africa.

Table 1

Fleas	No. collected	Percentage of collection
Xenopsylla brasiliensis (Baker)	723	71·72
Xenopsylla cheopis (Rothschild)	220	21·72
Leptopsylla aethiopicus (Rothschild)	18	1·77
Ctenocephalides felis strongylus Jordan	16	1·58
Echidnophaga gallinaceus (Westwood)	12	1·18
Dinopsyllus longifrons lypusus J. and R.	7	0·69
Pulex irritans Linnaeus	6	0·59
Ctenophthalmus cabirus Jordan	6	0·59
	1,008	

The dominant species, *X. brasiliensis*, was distributed and was dominant in urban and rural areas from sea-level to 6,000 ft., whereas *X. cheopis* was not found above 4,000 ft. *P. irritans* and *Ct. f. strongylus* were fleas of urban rats, but *D. l. lypusus*, *L. aethiopicus* and *Ct. cabirus* were confined to rats from the rural areas. The cosmopolitan *E. gallinaceus* was found in both urban and rural areas.

My thanks are due to the Director of Medical Services, Tanganyika, for permission to publish this communication; and to Dr. B. de Meillon, of the South African Institute for Medical Research, and Mr. G. H. E. Hopkins, of the Zoological Museum, Tring, for identification of the fleas.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, September 22

Institution of Mining and Metallurgy (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p.m.—Dr. Anton Gray: "The Future of Mineral Exploration" (Fourth Sir Julius Wernher Memorial Lecture).

Tuesday, September 23

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p.m.—Mr. James Moir: "Stereophonic Sound Systems".

Tuesday, September 23—Wednesday, September 24

Institution of Mining and Metallurgy (in co-operation with the United Kingdom Metal Mining Association, at 21 Tothill Street, London, S.W.1), at 10 a.m. daily—Symposium on "The Future of Non-Ferrous Mining in Great Britain and Ireland".

Tuesday, September 23—Thursday, September 25

Institution of Mechanical Engineers (at 1 Birdcage Walk' London, S.W.1)—International Conference on "Gearing".

Wednesday, September 24

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. A. I. Godfrey: "Statistics in Radio and Television Manufacture".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. M. Szwarc (Syracuse University): "'Living' Polymers".

Oil and Colour Chemists' Association, London Section (joint meeting with the Society of Dyers and Colourists, at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. J. L. Moilliet: "Surface Activity—the General Concept and some Consequences".

Wednesday, September 24—Friday, September 26

Institute of Petroleum Hydrocarbon Research Group—Mass Spectrometry Panel, and Committee E-14 of the American Society for Testing Materials in the Beveridge Hall, Senate House, University of London, Gower Street, London, W.C.1)—Conference on "Mass Spectrometry".

Wednesday, September 24—Friday, October 3

Industrial Fuel Efficiency Exhibition (at the National Hall, Olympia, London).*

Thursday, September 25, Friday, September 26, Tuesday, September 30 and Wednesday, October 1, from 10.30 a.m. to 12.30 p.m. daily—Series of Technical Meetings on "Lower Costs and Higher Production through Better Fuel Utilization".

Thursday, September 25—Friday, September 26

Institute of Biology (in the Lecture Hall, Royal Geographical Society, Kensington Gore, London, S.W.7), at 10 a.m. daily—Symposium on "The Effects of Pollution on Living Material".

Friday, September 26—Saturday, September 27

Institute of Physics, Electronics Group (at University College, London, W.C.1)—Meeting on "Solid State Memory and Switching Devices".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Resident Supervisor (with a degree in agriculture and a special interest in animal husbandry) for Certificate Courses in Agriculture—The Secretary, The North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (September 23).

Research Assistant (graduate in bacteriology) in Chemistry, to carry out routine growing of micro-organisms in connexion with a biosynthesis programme—The Registrar, The University, Manchester (September 29).

Senior Lecturer or Lecturer in Botany—The Registrar, The University, Manchester (September 30).

Lecturer (with a medical qualification) in Bacteriology at the Royal Infirmary, Glasgow—The Secretary of University Court, The University, Glasgow (October 10).

Lecturer (with an honours degree in mathematics or mathematical physics, lecturing experience, and preferably experience in some aeronautical subject and/or numerical methods) in the Department of Mathematics—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks (October 11).

Keeper of the Department of Geology—The Director, National Museum of Wales, Cardiff (October 24).

Chair of Solid State Physics tenable at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 27).

Lecturer in Physiology—The Secretary, The University, Aberdeen (October 31).

Lecturer in Psychology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturer or Assistant Lecturer in Biochemistry at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

Lecturer/Senior Lecturer in Pathology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturer (with a degree in science or agricultural science and interests in the fields of physical and inorganic chemistry) in Agricultural Chemistry (Physical and Inorganic) at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Chair of Electrical Engineering tenable at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (November 15).

Lecturer in Physics, and a Senior Lecturer or Senior Research Fellow in Theoretical Physics at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 28).

Ralston Professor of Zoology at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 15).

Agronomist at the West African Institute for Oil Palm Research, for research work on the cultivation of the oil palm; and Plant Physiologists (2), one to review present methods of production and initiate ways of increasing the supply of palm wine, and the other to carry out leaf analysis and other investigations into the nutrition of the oil palm—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/199/013.

Assistant Lecturer (Grade B) in Electrical Engineering, to assist in courses for O.N.C. and H.N.C. in electrical engineering; and an Assistant Lecturer (Grade B) in Applied Physics, for O.N.C. course developing to H.N.C. level in Session 1959–60—The Principal, Farnborough Technical College, Boundary Road, Farnborough, Hants.

Assistants (either sex, with a good reading knowledge of Russian or Italian, and preferably scientific interests), for abstracting papers in economic entomology—The Director, Commonwealth Institute of Entomology, 56 Queen's Gate, London, S.W.7.

Biochemist, basic grade (A.R.I.C. or B.Sc. with honours in chemistry or biochemistry)—The House Governor, Queen Elizabeth Hospital, Edgbaston, Birmingham 15.

Lecturer (with a good honours degree in chemistry or F.R.I.C.) in Inorganic Chemistry at Coventry Technical College—Director of Education, Council Offices, Coventry.

Research Assistant (with a good first degree in botany or horticulture, and preferably research experience and a higher degree), for work on the physiology of flowering in carnations—Prof. O. V. S. Heath, Department of Horticulture, The University, Reading.

Scientific Officer (with a first- or good second-class honours degree), to lead a section applying the techniques of gamma-ray spectrometry to the analysis of radioactive material and to expand the programme—Group Recruitment Officer (1193/34), United Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Technical Research Assistant in the Physiology Department—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

New Books

The STRENGTHS of CHEMICAL BONDS

Second Edition

By T. L. COTTRELL

Research on bond strengths has continued rapidly in the last few years, and much new information, covered by almost two hundred references to recent work, has been included in this second edition. In particular, important new results on the heats of atomization of carbon, nitrogen, sulphur, boron and silicon have required extensive revision of bond energy terms involving these elements. At the same time the discussion of dissociation energies has been brought up to date.

This book gives a full description of the experimental approach to the study of bond strengths that will commend itself to the theoretician who must assess experimental results and to those who are about to start research in the subject, or to anyone looking for values of bond strengths.

ELECTROCHEMICAL THERMODYNAMICS AND KINETICS

Editor-in-Chief: Professor G. VALENSI

These 60 edited papers are a record of the 8th Meeting of the International Committee of Electrochemical Thermodynamics and Kinetics (C.I.T.C.E.), 1956.

Working to an agreed programme, C.I.T.C.E., Commissions and Study Groups met in Madrid in 1956 to report research progress into corrosion and protection, semi-conductors, electrochemical kinetics, batteries and accumulators, experimental methods and electrochemical diagrams. This record forms an invaluable summary of current opinion and work within these fields.

Price 95*s.*

ESSENTIAL FATTY ACIDS

Editor: H. M. SINCLAIR, Ph.D.

Some thirty years ago it was shown that certain unsaturated fatty acids are needed in the diet of rats and therefore constitute vitamins. In the last year or two it has been found that these acids lower serum cholesterol and that deficiency of them may be relevant to certain very important clinical conditions such as atheroma and coronary thrombosis.

Our understanding of the structure and synthesis of fatty acids has increased enormously in recent years. Their chemical, biochemical and clinical aspects were thoroughly discussed at the Fourth International Conference on Biochemical Problems of Lipids and this volume of 42 edited papers adds considerably to current knowledge of this rapidly advancing subject.

LECTURES AND COURSES

WOOLWICH POLYTECHNIC

COURSES OF SPECIAL EVENING LECTURES IN HIGHER TECHNOLOGY

COMMENCING AUTUMN TERM—SESSION 1958-9

(a) ENERGY RESOURCES AND POWER UTILIZATION.

Four lectures commencing Wednesday, October 1, at 7 to 9 p.m. By H. HEYWOOD, D.Sc.Eng., Ph.D., A.C.G.I., Wh.Sch., M.I.Mech.E., M.I.Chem.E.

(b) ADVANCED MATHEMATICS I.

Twenty-eight lectures commencing Thursday, October 2, at 6.30 to 9 p.m. By J. I. SONN, B.Sc.(Eng.), A.M.I.E.E.

(c) ADVANCED MATHEMATICS II.

Twenty-eight lectures commencing Wednesday, October 1, at 6.30 to 9 p.m. By G. C. STALKER, M.A.(Edin.), M.A. (Cantab).

(d) INTRODUCTION TO THE MATHEMATICAL THEORY OF ELASTICITY AND PLASTICITY.

Twenty lectures commencing Tuesday, September 30, at 7 to 9 p.m. By D. E. R. GODFREY, M.Sc., Ph.D., A.F.R.Ae.S.

(e) FUNCTIONS AND METHODS OF MATHEMATICAL PHYSICS.

Twenty-eight lectures commencing Tuesday, September 30, at 6.30 to 9 p.m. By—Lecturer to be appointed.

(f) ELECTRO-MAGNETIC THEORY.

Twenty-eight lectures commencing Monday, September 29, at 6.30 to 9 p.m. By K. E. PITMAN, M.Sc., A.R.C.S.

(g) ELECTRONICS FOR MECHANICAL ENGINEERS.

Twenty lectures commencing Monday, September 29, at 7 to 9.30 p.m. By K. B. REED, B.Sc., A.M.I.E.E.

(h) INTRODUCTION TO SERVO-MECHANISMS.

Twenty lectures commencing Tuesday, September 30, at 7 to 9.30 p.m. By K. B. REED, B.Sc., A.M.I.E.E.

(i) NUCLEAR PHYSICS.

Twelve lectures commencing Wednesday, October 29, at 7 to 9 p.m. By K. V. HYDE, B.Sc.

(j) RECENT ADVANCES IN SYNTHETIC ORGANIC CHEMISTRY.

Six lectures commencing Tuesday, October 21, at 7.15 to 8.30 p.m. By R. SLACK, M.A., D.Phil.

(k) PESTS OF FOODSTUFFS AND STORED PRODUCTS.

Twelve lectures commencing Monday, October 6, at 6.30 to 8 p.m. By C. S. WOOD-BAKER, M.Sc., Ph.D., F.Z.S., F.R.E.S.

(l) INSECT PESTS AND FUNGAL DISEASES IN HORTICULTURE AND MARKET GARDENING.

Twenty-four lectures commencing Monday, October 6, at 6.30 to 8 p.m. By G. M. BROWN, B.Sc., A.R.C.S., and C. S. WOOD-BAKER, M.Sc., Ph.D., F.Z.S., F.R.E.S.

(m) MICROSCOPY AND ITS APPLICATIONS.

Twelve lectures commencing Monday, October 6 at 7 to 9 p.m. By H. HEYWOOD, D.Sc.Eng., Ph.D., A.C.G.I., F.R.Micr.S., Wh.Sch., M.I.Mech.E., M.I.Chem.E., A. J. HOLLOWELL, B.Sc., and others.

(n) DISEASES AND PESTS OF TIMBER.

Eight lectures commencing Thursday, October 23, at 6.30 to 8 p.m. By C. S. WOOD-BAKER, M.Sc., Ph.D., F.Z.S., F.R.E.S.

(o) PROBLEMS IN ADVANCED METROLOGY.

Six lectures commencing Wednesday, November 5, at 7 to 9 p.m. By B. FERGUSSON, B.Sc.Eng., Ph.D., A.M.I.-Mech.E.

(p) WELDING AND PLASTICS FOR PLUMBERS' WORK.

Eight lectures commencing Monday, September 22, at 7 to 9 p.m. By W. R. BURCHMORE, M.R.San.I.

(q) PUNCHED CARDS IN OFFICE AND FACTORY.

Eight lectures commencing Wednesday, October 8, at 7 to 9 p.m. By L. R. CRAWLEY, M.O.M.A., M.S.I.E., A.M.I.I.A., A.I.Prod.E.

(r) INDUSTRIAL RELATIONS TO-DAY.

Eight lectures commencing Wednesday, October 8, at 7 to 9 p.m. By MARY S. COUSINS, M.A., Dip.Social Studies, M.I.P.M.

(s) RECENT CHANGES IN CONSTITUTIONAL LAW.

Eight lectures commencing Thursday, October 9, at 7 to 9 p.m. By—Lecturer to be appointed.

(t) ORGANIZATION AND METHOD IN THE MODERN OFFICE.

Eight lectures commencing Friday, October 10, at 7 to 9 p.m. By H. W. S. MEAD, A.C.W.A.

(u) DESIGN AND FORM OF INDUSTRIAL PRODUCTS.

Six lectures commencing Monday, November 3, at 7.30 to 9.30 p.m. By Leading Industrial Designers.

(v) MODERN ART.

Six lectures commencing Thursday, November 6, at 7.30 to 9.30 p.m. By Well-known writers and critics.

FEES: Courses (b), (c), (d), (e), (f), (g), (h), (l), £2.
Courses (i), (k), (m), (n), (p), (q), (r), (s), (t), £1.
Courses (a), (j), (o), (u), (v), 10s.

ENROLMENT: By personal application from 9 a.m. to 8.30 p.m. or by postal application to the Secretary.

Middlesex County Council Education Committee

BRUNEL COLLEGE OF TECHNOLOGY,
WOODLANDS AVENUE, ACTON, W.3

Principal: Dr. J. Topping, M.Sc., Ph.D., D.I.C., F.Inst.P.

DEPARTMENT OF PHYSICS

Head of Department: C. A. Hogarth, B.Sc., Ph.D., A.Inst.P.

EVENING LECTURES—AUTUMN 1958

DISLOCATIONS IN SOLIDS

Thursdays—6.30 to 7.45 p.m. Twelve lectures commencing September 25, 1958.
Lecturer: R. L. BELL, B.Sc., Ph.D., Lecturer in Metallurgy at Imperial College

BIOLOGICAL EFFECTS OF NUCLEAR AND ALLIED RADIATIONS

Tuesdays—7.30 to 8.45 p.m. Six lectures commencing October 21, 1958.
Lecturer: E. A. WRIGHT, M.D., M.R.C.P., University Reader in Pathology at St. Mary's Hospital Medical School

ULTRASONICS

Wednesdays—6.30 to 9.30 p.m. Twenty lectures commencing October 8, 1958.
Lecturer: J. BLITZ, M.Sc., A.Inst.P., Lecturer in Physics, Brunel College of Technology

X-RAY CRYSTALLOGRAPHY

Tuesdays—6.30 to 9 p.m. Ten lectures commencing September 30, 1958.
Lecturer: J. I. MITCHELL, M.Sc., A.Inst.P., Lecturer in Physics, Brunel College of Technology

THE PHYSICS OF NUCLEAR ENGINEERING

Mondays—6.30 to 8.30 p.m. Thirty lectures commencing October 6, 1958.
Lecturer: J. W. WARREN, M.Sc., Ph.D., Senior Lecturer in Physics, Brunel Colege of Technology

AN INTRODUCTION TO THE PHYSICS OF TRANSISTORS

Mondays—6.30 to 7.30 p.m. Nine lectures commencing October 6, 1958.
Lecturer: C. A. HOGARTH, B.Sc., Ph.D., Brunel College of Technology.

C. E. GURR, M.Sc., Ph.D.,
Clerk to the Governing Body.

BOROUGH POLYTECHNIC

BOROUGH ROAD, S.E.1

ELECTRONICS AT LOW TEMPERATURES

A course of 12 lectures will be given at the Borough Polytechnic on Friday evenings at 7 p.m., commencing October 3, 1958. The lectures will be given by specialists from Industry and the Universities and the aim of the course is to introduce the Physicist and Electronic Engineer to some of the recent developments in what promises to become an important field of application. Lectures will be given in Low Temperature Physics and in the management of a low temperature laboratory as well as in the practical electronics applications.

Further information and application form may be obtained from the Secretary.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7

CHEMICAL ENGINEERING DEPARTMENT

A course of four lectures on "Trapped Radicals" will be given by Dr. G. J. Minkoff on Mondays at 2 p.m., commencing October 20, 1958.

Further particulars from the Registrar, Imperial College, London, S.W.7.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7

CHEMICAL ENGINEERING DEPARTMENT

A course of six lectures on "The Design, Testing and Protection of Pressure Vessels" will be given by Mr. K. E. Bett on Mondays at 3.15 p.m., commencing October 20, 1958.

Further particulars from the Registrar, Imperial College, London, S.W.7.

UNIVERSITY COLLEGE LONDON, GOWER Street, London, W.C.1. Applications for B.Sc. (Special) Degree course in Chemistry, commencing October, 1959, must reach the Tutor to Science Students by December 31, 1958 (quote TS/C).—Selected applicants, who will be notified individually, will be required to attend the written examination and an interview on both Thursday and Friday, January 22 and 23, 1959, from 9 a.m. to 5 p.m.

OFFICIAL APPOINTMENTS

HAMPSHIRE EDUCATION COMMITTEE

FARNBOROUGH TECHNICAL COLLEGE

Principal: Mr. R. D. Peggs, O.B.E., M.A., M.I.Mech.E., F.R.Ae.S.

Applications are invited for the following posts:

(1) Assistant Lecturer (Grade B) in Electrical Engineering to assist in courses for O.N.C. and H.N.C. in Electrical Engineering. Industrial experience preferable.

(2) Assistant Lecturer (Grade B) in Applied Physics for O.N.C. course developing to H.N.C. level in Session 1959/60. Industrial experience preferable.

The salary for the posts will be in accordance with the Burnham Scale—Grade B (men) £650 by £25 to £1,025 with the usual allowances for training, qualifications and industrial experience, e.g., £125 for a good honours degree.

Further particulars and application forms may be obtained from the Principal, Farnborough Technical College, Boundary Road, Farnborough, Hants, to whom they should be returned as soon as possible.

R. M. Marsh. County Education Officer, The Castle, Winchester.

MATHEMATICIAN OR STATISTICIAN REquired for appointment as a Statistical Engineer in the System Operation Branch at Central Electricity Generating Board Headquarters, London, S.E.1. Duties include investigations requiring the application of advanced statistical and probability methods to engineering problems associated with the operation of a large interconnected electricity supply system, with particular reference to short-term load estimation and to the study of the effect of weather on system load. Computing assistance will be provided and access to the facilities of a large electronic computer will be available. Candidates should have a knowledge of statistics and should hold a university degree in mathematics or statistics. A knowledge of meteorology would be an advantage. Salary on a scale within the range £1,210 to £1,795 per annum according to duties and responsibilities.—Applications, stating age, qualifications, experience, present position and salary, to I. G. Ellis, Personnel Officer, 24/30 Holborn, London, E.C.1, by October 3. Please mark envelopes "Confidential" and quote ref. No. N./268.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

SOIL MECHANICS SECTION

APPOINTMENT OF SOIL STABILIZATION CHEMIST

Applications are invited for appointment to a position of Soil Stabilization Chemist with the Organization's Soil Mechanics Section located at Box Hill, Victoria. The appointee will be located in Melbourne but will be expected to observe soils and soil conditions in various parts of Australia. The Section has undertaken a major programme of research into the principles and practices of soil stabilization with particular reference to Australian soils and the Australian environment. The programme is based upon pedological concepts and is supported, in matters of pedology and soil chemistry, by the Division of Soils, C.S.I.R.O. It is proposed that each of the disciplines of soil physics, soil chemistry, and soil mechanics, as applied specifically to the problems of soil stabilization, will be developed within the Soil Mechanics Section. The appointee would be expected to take responsibility for the chemical aspects of this programme and to work in close liaison with the associated disciplines within and without the Section. If sufficiently experienced, the appointee would be expected to assume the major control, under the general direction of the Officer-in-Charge, of the work of this group. Applicants should possess a university honours degree in science with chemistry as a major subject, or equivalent qualifications. Advanced training and postgraduate research experience is desirable, particularly in the field of colloid chemistry. A familiarity with soil chemistry and a basic training in physics and/or geology would be an advantage. Dependent upon qualifications and experience, commencing salary will be determined within the salary ranges of Research Officer, £A.1,326 to £A.1,951 per annum, or Senior Research Officer, £A.2,061 to £A.2,336 per annum. Salary for a female appointee would be £A.170 per annum less than the corresponding male rates. The appointment will be conditional upon a satisfactory medical examination and confirmation of appointment carries with it Commonwealth Superannuation Fund or Commonwealth Provident Account privileges. Fares to Australia, including those of wife and dependent family, will be provided by the Organization. Details may be discussed with the undersigned.

Applications, quoting Appointment No. 277/3, and stating full name, place, date and year of birth, nationality, marital state, present employment, details of qualifications and experience, and of war service, if any, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach the undersigned, from whom further particulars may be obtained, by October 18, 1958.

E. J. DRAKE,
Chief Scientific Liaison Officer.
Australian Scientific Liaison Office,
Africa House, Kingsway, W.C.2.

UNIVERSITY OF READING

Research Assistant wanted for work on the physiology of flowering in carnations. The appointment would be, in the first instance, for one year only. Candidates should have a good first degree in botany or horticulture; research experience and a higher degree an advantage. Salary between £450 and £600 per annum according to age and experience.

Applications to Professor O. V. S. Heath, Department of Horticulture, The University, Reading.

SENIOR SCIENTIFIC AND SCIENTIFIC Officers, required at Government Communications Headquarters, Cheltenham, for telecommunications and electronic research in following fields: V.H.F. receiver design and microwave techniques; propagation trials; applications of semi-conducting devices; high speed electronic switching; data storage and handling; computer programming, and operational research. Candidates must normally be natural born British subjects of natural born British parents. First- or second-class honours degree in physics, mathematics or engineering or equivalent, at least three years' postgraduate experience for Senior Scientific Officer. Salaries for men (provincial rates) Senior Scientific Officer, £1,130 to £1,330; Scientific Officer, £595 to £1,050 (according to age and qualifications). Appointments unestablished but opportunities to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A147/8A.

ESSEX EDUCATION COMMITTEE

MID-ESSEX TECHNICAL COLLEGE

MARKET ROAD, CHELMSFORD

The following teachers are required in the Science Department from January, 1959:

(a) Senior Lecturer in Applied Physics. Candidates should hold a good honours or higher degree, be corporate members of the Institute of Physics, and having teaching as well as industrial and/or research experience.

Salary scale: £1,350 by £50 to £1,550 per annum.

(b) Lecturer in Physics. Candidates should have a good honours degree or equivalent, together with teaching, research, or industrial experience, and be able to offer specialized knowledge of a branch of Applied Physics.

Salary scale: £1,200 by £30 to £1,350 per annum.

(c) Assistant, Grade B, for Mathematics. Applicants should be graduates, and some previous teaching experience is desirable. Duties will involve work in Degree and H.N.C. courses.

Salary: £650 by £25 to £1,025 with additions for graduation (or equivalent) and approved training. Increments within scale for previous teaching service, approved industrial experience and War/National Service.

Details and application forms (stamped addressed foolscap envelope) from the Clerk to the Governors at the College.

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for a National Coal Board Postdoctoral Fellowship in Physical Chemistry. The research work to be undertaken is connected with the study of solids by a number of techniques such as mass spectroscopy. The salary will be £700 to £800 per annum according to age and experience.

Applications (two copies) should be sent not later than October 31, 1958, to the Registrar, the University, Edgbaston, Birmingham, 15.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7

Research physicist or engineer, preferably with knowledge and aptitude for hydrodynamics, required to undertake model research on fluid flow. Work could lead to higher degree. Salary £450 to £850 per annum, according to experience.

Apply, with names of two referees, to Meteorology Department.

FOURAH BAY COLLEGE

UNIVERSITY OF DURHAM

SIERRA LEONE

Applications are invited for the post of Senior Lecturer or Lecturer in Geography. Qualifications: good honours degree and teaching experience. Salary scale: Senior Lecturer, £1,700 by £75 to £2,150; Lecturer, £965 by £50 to £1,365; E.B., £1,415 by £75 to £1,715. Entry point according to qualifications and experience. Other conditions include children's allowances (maximum £300), passages on appointment and annual leave, part-furnished accommodation at rental not exceeding 7½ per cent of salary.

Further information from Secretary, Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2, to whom applications (six copies) giving age, qualifications, and experience and naming three referees should be sent by October 6, 1958.

UNIVERSITY OF DURHAM

Applications are invited for the post of Assistant Appointments Officer. The person appointed will be concerned with students and graduates in science and also probably agriculture. Candidates should have a degree, preferably in science, and experience of work in fields where graduate scientists are commonly employed. Starting salary will be within the range £900 by £50 to £1,350 (bar), the scale then rising to £1,650. F.S.S.U. membership is compulsory.

Further particulars of the post may be obtained from the Registrar of the University at 46 North Bailey, Durham, with whom twelve copies of application should be lodged not later than September 27, 1958. (Candidates outside the British Isles may submit one copy only.)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

Assistant for Information Service. Duties include assisting with public relations activities, subediting, and internal information work. Applicants preferably should hold a science degree, and a knowledge of languages would be an advantage. Appointment will be made within Assistant Experimental Officer grade: £478 per annum (at age 21) to £645 (at age 26 or over), scale maximum £800 scale for women slightly lower. Pension scheme.

Applications, naming two referees, to Secretary, N.I.R.D., Shinfield, Reading. Quote ref. 58/25.

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

MATHEMATICIAN for NUMERICAL ANALYSIS

A Mathematician interested in the development of methods of Numerical Analysis is required for a senior post which carries responsibility for all the research in numerical analysis at Aldermaston The computing equipment available is unique in Great Britain and includes an I.B.M. 704, a Deuce, and a Ferranti Mark 1*.

Candidates should have a first-class honours degree in Mathematics; preference will be given to those whose experience of Numerical Analysis has been particularly concerned with partial differential equations.

The salary paid will be in the range £2,200–£2,600 p.a. Contributory superannuation scheme. A modern house with garage will become available for married officers living beyond daily travelling distance.

Please send a postcard for application forms to

The Senior Recruitment Officer,
A.W.R.E., ALDERMASTON, BERKS.
Please quote ref. No. 2024/34

CENTRAL ELECTRICITY GENERATING BOARD

COMPUTORS are invited to apply for appointment as Technical Assistant (Statistics) in the Statistics Section of the Generation Operation Branch located at Holborn, E.C.1. Salary £10 7s. to £12 5s. 6d. per week.

Candidates should have a General Certificate of Education at Advanced level in Mathematics, or equivalent, and practical experience of calculating machinery.

Applications, stating age, qualifications, experience, present position and salary, should be forwarded to I. G. Ellis, Personnel Officer, 24/30 Holborn, London, E.C.1, so as to arrive not later than September 27. Envelopes should be marked "Confidential"—Ref. N./264.

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISIONS OF SOILS

APPOINTMENT OF PEDOLOGIST AND SOIL SURVEYOR

Applications are invited for appointment to a position of Pedologist and Soil Surveyor with the Organization's Division of Soils located at Deniliquin, New South Wales. The appointee will be required to determine which soil characteristic and value is indicative of crop suitability in particular districts and for a variety of crops. This work requires the development of a new line of investigations which will render soil surveys more serviceable. The work, initially, will be concerned with determining soil characteristics indicative of the response of irrigated pastures in N.S.W. Applicants should possess a university honours degree in science or agricultural science together with some previous research experience preferably in soils investigations. Competence in statistical techniques is desirable. Commencing salary is dependent upon the appointee's qualifications and experience and will be determined within the salary range of Research Officer, £A.1,326 to £A.1,951 per annum. Salary for a female appointee would be £A.170 per annum less than the corresponding male rates. The appointment will be conditional upon a satisfactory medical examination and an initial probationary period of up to twelve months may also be specified. Confirmation of appointment carries with it Commonwealth Superannuation Fund or Commonwealth Provident Account privileges. Fares to Australia, including those of wife and dependent family, will be provided by the Organization. Details may be discussed with the undersigned.

Applications, quoting Appointment No. 270/166 and stating full name, place, date and year of birth, nationality, marital state, present employment, particulars of qualifications and experience, and of war service, if any, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach the undersigned, from whom further particulars may be obtained, by October 18, 1958.

E. J. DRAKE,
Chief Scientific Liaison Officer.
Australian Scientific Liaison Office,
Africa House, Kingsway, W.C.2.

THE ROYAL COLLEGE OF SCIENCE AND TECHNOLOGY,

GLASGOW

(Affiliated to the University of Glasgow)

CHAIR OF METALLURGY

The Governors of the Royal College of Science and Technology invite applications for the Chair of Metallurgy, which will become vacant on April 1, 1959, on the retirement of the present holder, Professor R. Hay. The salary is on a scale £2,400 by £100 to £2,700. Forms of application and particulars of the appointment may be obtained from the Secretary.

THE SECRETARY OF STATE FOR SCOTland invites applications for the Regius Chair of Botany in the University of Aberdeen. The person appointed will be expected to take up his duties on October 1, 1959.—Three copies of applications, accompanied by the names of three referees, should reach the Private Secretary, St. Andrew's House, Edinburgh, 1, not later than November 10, 1958. A note of the conditions and appointment will be supplied on request.

AGRICULTURAL DEPARTMENT

TRINIDAD

ENTOMOLOGIST

To carry out research on biology and control of insect pests of coconuts and to co-operate in assessing their importance as vectors of Red Ring Disease. Candidates must have a good honours degree in Natural Science and should have had some research experience in entomology. Appointment is on contract/gratuity terms for three years in the first instance with salary in scale £950 to £1,450 per annum. Gratuity of £25 to £37 10s. for each completed period of three months' satisfactory service. Free return passages for officer, wife and children not exceeding five persons in all. Government quarters, when available, at moderate rental. House allowance payable if quarters not available.

Apply, giving brief particulars to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD 63/38/01.

NORTHERN POLYTECHNIC

HOLLOWAY, LONDON, N.7

The Governing Body invites applications for appointment as Principal of the Northern Polytechnic. Candidates should possess high academic qualifications and appropriate educational and administrative experience. Salary scale: £2,350 rising by annual increments of £100 to £2,650 per annum, plus London allowance. Duties will commence on September 1, 1959, or such earlier date as may be agreed. The Northern Polytechnic is a major Regional Technical College. To meet current needs and to provide for future development, a large site adjacent to the Polytechnic is now being acquired for a substantial extension.

Form of application, together with full particulars, will be forwarded on request, and should be returned to me, duly completed, not later than October 31, 1958.

R. H. CURRELL, A.C.A.,
Clerk.

REACTOR PHYSICISTS

are required by the

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

(Industrial Group)

Risley, Warrington, Lancashire,

in the Central Technical Services, which is responsible for the detailed performance calculation of Industrial Group projects and for collaboration in this respect with industrial firms and Electricity Boards, undertaking nuclear work.

A number of vacancies exist in the rapidly expanding Thermal Reactor Neutronics Section which are of particular interest to men and women physicists and mathematicians who wish to enter the atomic energy industry.

The work covers many topics, including the estimation of reactor parameters, the economic aspects of nuclear power stations and the subjects of reactor kinetics and automatic control which are becoming of great significance. Close liaison is maintained with experimental work carried out at other Authority establishments and many opportunities arise for visiting these sites. Much of the work requires the use of automatic computers and a programming and computing service is being provided. A knowledge of nuclear physics or the mathematics of reactors is not essential as there are considerable opportunities for training and particular efforts are made to give each member of the staff a wide range of experience.

A first- or second-class honours degree, or equivalent, is essential.

Salary between

£1,460 and £2,080,
£1,215 and £1,425,
£645 and £1,120

according to qualifications and experience.

Good relevant research experience is essential for apointment in the higher scales.

Contributory Pension Scheme.

Housing or assistance towards legal expenses on house purchase may be available.

Send postcard for application form, quoting reference 2628, to Recruitment Officer at above address.

Closing date: October 13, 1958.

ASSISTANT DIRECTOR

required at the National Coal Board's Mining Research Establishment, Worton Hall, Isleworth, Middlesex. This Establishment employs some 200 scientists and technologists, a large proportion being physicists and mechanical engineers, on research, embracing all aspects of underground mining, e.g., coal winning, rock working, underground transport, strata control, environmental conditions, instruments for measurement and control and metallurgical problems.

Applicants should be Mechanical Engineers with an interest in applied mechanics, or Physicists having a good academic record with considerable experience both in research and its direction including planning, budgetary control, interpretation of results and the application of conclusions by development and user organizations.

The appointment is superannuable, and salary depending on qualifications and experience will be not less than £2,200.

Write to Staff Manager (X.1245), N.C.B., Hobart House, Grosvenor Place, London, S.W.1, stating age, education, qualifications and experience, before September 30, 1958.

UNIVERSITY OF DURHAM

KING'S COLLEGE

NEWCASTLE UPON TYNE

A Biochemical Technician is required in th Physiology Department of the Medical School, t take charge of the preparation of material for bic chemical classes for medical, dental and scienc students, and to assist, if required, in researc work of a biochemical nature. The appointmer will be on the Technician Grade (for which th salary scale is £420 to £570 per annum) or on th Senior Technician Grade (for which the sala scale is £590 to £690 per annum). The Grade t which the appointment is made, and the point c entry on the salary scale will be determined b age and experience.

Application, in writing, should be made to Pro fessor A. A. Harper, Department of Physiolog Medical School, King's College, Newcastle upo Tyne, 1.

UNIVERSITY OF DURHAM

KING'S COLLEGE,

NEWCASTLE UPON TYNE

DEPARTMENT OF PHYSIOLOGY

The Council of King's College invite applic tions for the post of Lecturer or Demonstrator i Physiology. The lecturer or demonstrator will b concerned chiefly with dental teaching, but may b asked to take part in the teaching of medical an science students. Applicants should have a med cal or dental qualification or an honours degr in physiology or biochemistry. The grade an commencing salary will be determined on the bas of the qualifications and experience of the a pointee. Appointments on the Demonstrat Grade are for one year in the first instance b renewable up to a maximum of three years. Th salary ranges are as follows: medical £700 t £1,000; non-medical, under 26, £650 to £700, ov 26, £700 to £750. There are annual increments c £100 for medical and £25 for non-medical demo strators. The salary ranges on the Lecturer Gra are as follows: medical £950 by £100 to £1,650 non-medical £900 by £50 to £1,650.

Twelve copies of application, together with th names of three persons to whom reference may b made, should be submitted not later than Octob 11, 1958, to the undersigned from whom furth particulars may be obtained.

G. R. HANSON,
Registrar of King's Colleg

NYASALAND

ASSISTANT CONSERVATOR OF FOREST

In addition to the general duties of an Assista Conservator of Forests he will also be required f practical surveying duties within Forest Reserve Candidates must have a university degree i forestry, experience or training in surveying a advantage. Appointment on probation to th permanent establishment with pensionable emol ments in scale £895 to £1,850 per annum. Fr passages on appointment and leave for officer, wif and children up to three adult passages in al Furnished quarters, normally available at modera rental.

Apply, giving brief particulars, to Director c Recruitment, Colonial Office, London, S.W.1 quoting BCD.61/4/01.

Fact finding

Laboratory tests at the N.C.B. Coal Research Establishment had proved that 'froth-flotation' was the most efficient method of cleaning fine coal before making it into high-grade smokeless fuel.

But before the process could be put on an industrial basis the scientists needed to know much more about it. So they put photography to work, to get the facts.

A 'Kodak' High-Speed Cine Camera was used, with a beam-splitting device between camera and object to give two pictures on each frame, one at right angles to the other. The film was shot on 16 mm Cine-Kodak 'Tri-X' Film at 3,000 fps, and projected at normal speed. The scientists then examined the action of the froth bubbles on the coal particles, and saw *why* the method was so efficient.

It is significant that more and more laboratory photographers are using 'Tri-X' film for very high speed cinematography where clear reproduction of minute details is essential.

ADMINISTRATION OF SCIENCE IN BRITAIN AND THE UNITED STATES

THE papers presented to the Sixth Conference on Scientific Manpower, held at Indianapolis last December in conjunction with the 124th annual meeting of the American Association for the Advancement of Science, have recently been published by the National Science Foundation*, with an introductory account reviewing the major developments which affected the scientific man-power situation in the United States during 1957. There was some easing of the demand for scientists and engineers during the year as a result of economic readjustment, while there were increases of about 11 per cent in the number of first-level degrees awarded in natural science and of about 19 per cent in bachelors' degrees in the engineering field in 1956–57 over the previous year. There was growing public awareness of the significance of scientific and technical training at all levels to the welfare and economic growth of the nation, and this introductory survey emphasizes that temporary shifts in the supply–demand interrelation have not altered the underlying influence of science and technology on the national economy.

It will thus be seen that many of the same points are being emphasized in the United States as have been stressed in the presidential address to the British Association and on other occasions in Great Britain, when the bearing of education on science and technology was discussed. This is particularly noticeable in the papers contributed to the Manpower Conference, the broad theme of which was "Scientists and Scientific Research in a Changing Economy". In the first of these, Y. Brozen, of the University of Chicago, discussing scientific advance as a factor in economic change, presents evidence indicating that a rapid increase in the output of scientists and expenditure on research is required if the United States is to make the best use of its savings available for investment, and that care must be taken not to stifle expenditure on scientific work directly connected with research, if the military effort is to be supported with maximum efficiency. Research which has no direct relation to defence may do more to increase military output than that directly related. He sees little need for additional Government funds for research, but suggests less Government expenditure on applied and more on fundamental research. The bottleneck in research to-day is not money but personnel.

This, too, is a point that has been made repeatedly in Britain, and it is a major reason for current concern as to the disposition of our own research effort, both pure and applied. It may be true that, as J. F. Dewhurst observes in "America's Needs and Resources", technology is a primary resource, and that without it all other resources would vanish, but it could equally be argued that science itself is the ultimate resource. Without an appropriate balance between science and technology, however, the development of both is impeded, and in such a world of technology as that we have now entered the determination of that balance grows ever more difficult.

It is a matter not simply of appropriate organization for the disposition of resources and the control of their expenditure, but increasingly of sound judgment. The first is the reason why a recently issued report of the Select Committee on Estimates is of special interest to the scientist and technologist, the second a matter of appropriate education. Both points receive attention in this series of papers, notably in the second, and largest of the six, in which Dr. J. W. Feiss, of the Kennecott Copper Corporation, reviews the new and changing activities of scientists and the implications. He suggests that the proportion of 16 per cent of scientists engaged in science teaching is too low, though accepting that in view of the greater importance of quality of teaching a figure of 15–20 per cent may be reasonable. It is equally clear that greater mobility of both the scientist and technologist should be encouraged, and this should be a definite purpose in our higher education policy to further. The education of the public is also important, and Dr. Feiss urges that scientists must increasingly discharge this responsibility through the Press, radio and television. Scientific writers are needed to interpret to the public in simple language the complex technology of to-day and supply the need for information, for guidance and answers to the questions put by the man in the street. Here the British Association, for example, might well be increasingly concerned with the effectiveness of its annual meetings and other activities in discharging such a function.

Mr. W. D. Carey's discussion of the support of scientific research emphasizes that the direction of Government support of research is, in the United States, largely in the hands of scientists themselves, but points out that, as corollary, with such power and responsibility must go a greater understanding of decision-making problems in the Government generally and a perspective of the whole within which scientists must work. Finally, he urges that the ties between Government and science require strengthening but by methods that render science and education enduring and free institutions in their own right, and this involves thinking out a comprehensive public policy for the partnership of science with Government. Prof. H. E. Langenecker's paper, "New Dimensions in Training Scientists", likewise reflects concern over the relations between Government, education and science, and particularly over the difficulty of seconciling increasing Federal support with freedom of choice, of thought and discussion. The universities and colleges are already receiving about 1,000 million dollars a year of Federal funds for purposes remote from higher education itself, and he suggests that it may be desirable to increase the allocations in some categories, such as research grants of the type where the university retains the decision at the expense of those which make the university a faculty leased by the Government to do its own work. The problem of advance planning and continuity of support so far as Federal funds for research are concerned has not yet been satisfactorily resolved, and it is also necessary to consider new forms of assistance.

---

* National Science Foundation, Washington. Scientific Manpower, 1957: Papers of the Sixth Conference on Scientific Manpower. Pp. iii+46. (Washington, D.C.: National Science Foundation, 1958.)

Neither Mr. Carey, himself of the Bureau of the Budget, nor Prof. Langenecker (of the University of Illinois) expressly refers to the University Grants Committee, but it is obvious that they are considering the practicability of some device, appropriate to Federal conditions, which would strengthen the continuity and independence of fundamental research, particularly in the universities. It is interesting to note that a Government official, after expressing the opinion that in fundamental research and in other areas of development Government support, under recent conditions, has not fluctuated widely, so strongly advocates closer association of the scientist with policy and the making of decisions. None the less, the publication of the study by C. V. Kidd, of the National Institutes of Health, of the relation between Federal funds for research and the universities of America, to which Mr. Carey refers, should be of considerable interest in Britain. Apart from these questions of administration, with which both the Select Committee on Estimates and the Committee of Public Accounts have been preoccupied, there are other dangers to university work and autonomy, to which Prof. Langenecker more specifically refers, which apply equally to British universities and which, at a time of expansion and considerable stress, could be the more insidious and distorting.

Perhaps the point in Prof. Langenecker's paper which deserves to be most widely noted and considered in Britain is that in which he directs attention to what is being done for the improvement of learning and teaching. The new responsibilities and programme of the National Science Foundation appear as yet to have received comparatively little attention in Britain, but they point to possibilities that are highly significant at a time when the supply of teachers is the real bottleneck in the expansion of higher technological and of technical education—indeed, of education at all levels. Any means of making the most effective use of a limited and indeed scarce resource should be explored as carefully and urgently as the possibilities of expanding the supply, and it is the note of urgency with which the shortage is being tackled in the United States as well as the novelty and range of the efforts being made to improve the situation that should compel examination in Britain in the light of our own needs and conditions.

Of the remaining papers it should suffice to note that R. D. Bennett, of the General Electric Company, considers very briefly the contribution of large research centres to the training of scientific workers. Qualitatively this does not differ greatly in the United States from the contribution they make in Britain, but its dependence upon an adequate educational basis in the schools is emphasized. The concluding paper, by T. J. Mills, of the National Science Foundation, on comparative salary-levels of scientists deals with United States conditions and is admittedly incomplete. Geologists, physicists and meteorologists appear to be the higher paid scientists on the average, astronomers, mathematicians, biologists and psychologists coming at the other end of the scale; comparative data for chemists were not available. Some doubt is expressed whether the material rewards of a scientific or technical career are sufficient to ensure a continuing flow of new entrants in the numbers necessary to maintain or increase the supply.

COLLECTED WORKS OF MAX PLANCK

Physikalische Abhandlungen und Vorträge

Von Max Planck. (Aus Anlass seines 100 Geburtstages (23 April 1958), herausgegeben von dem Verband Deutscher Physikalischer Gesellschaften und der Max-Planck-Gesellschaft zur Förderung der Wissenschaften e.V.) Band 1: Pp. xv+776. Band 2: Pp. xi+716. Band 3: Pp. xii+426. (Braunschweig: Friedr. Vieweg und Sohn, 1958.) 150 D.M.

THIS work, consisting of three large volumes, has been published to celebrate the one hundredth birthday of Max Planck, one of the greatest men of science of all time. It contains his published scientific papers and the lectures and addresses which he delivered on various occasions, as well as a few addresses given in his honour by such distinguished men as Sommerfeld, Debye, von Laue and others.

It is beautifully produced, as indeed one would expect, coming as it does from the famous old firm of Friedr. Vieweg und Sohn in Brunswick. As von Laue indicates in his short preface, Planck began by an intensive study of the work of Rudolph Clausius, who introduced the notion of 'entropy' and who, it may be said parenthetically, was greatly influenced by Clapeyron (*vide* p. 123 of Browne's translation of "Mechanischetheorie der Wärme").

Most of the papers in Vol. 1, though not all of them, deal with thermodynamics, and there is no doubt that long reflexion on thermodynamical problems prepared the way for Planck's crowning achievement: the solution of the problem of the distribution of energy in the normal spectrum and the associated discovery of the elementary quantum of action.

Looking back, one can now appreciate that if Planck had known and attached any value to Hamilton's discovery of the identity in form of the laws of geometrical optics and those of (Newtonian) mechanics he might indeed have discovered wave mechanics by extending the identity in form from the narrow domain:

[geometrical optics]——[Newtonian mechanics]

to the more extensive domain:

[optics in the widest sense]——[an appropriately widened type of mechanics]

Until Born suggested, correctly as I believe, that the wave formulæ in quantum mechanics are simply expressions of probabilities, Planck, like everyone else, found insuperable difficulties in reconciling the corpuscular features, for example, of light, with its very marked undulatory characteristics. This appears in a paper on the synthesis between wave mechanics and corpuscular mechanics, published in 1940 (*vide* Vol. 2, p. 685). Naturally he could not then appreciate the significance of the fact that the corpuscular aspect only appears when sufficiently small numbers of particles are involved and the wave phenomena (as in Sir Geoffrey Taylor's experiments) when enormous numbers are dealt with. With enormous numbers probabilities approach certainties, as the success of insurance companies indicates.

At the end of Vol. 3 is the address delivered by Max von Laue at Planck's graveside, some personal memories of Planck by Dr. Otto Hahn, and a short essay on his life-work by von Laue.

As the originator of the quantum theory Planck's fame will endure and his name will always rank with those of Newton, Clerk Maxwell and Einstein. But there is something more to be said about him: he was a kindly, good man—a great gentleman who endured patiently and bravely the sorrows and suffering which overwhelmed him in his later life. He was a real friend to me and I shall always remember one of his favourite sayings:

"Man muss Optimist sein". W. WILSON

OPERATIONAL RESEARCH

Proceedings of the First International Conference on Operational Research, Oxford, 1957

(Organized by the Operational Research Society, United Kingdom; The Operations Research Society of America; and the Institute of Management Sciences.) Pp. viii + 526. (London: English Universities Press, Ltd., 1957. Published for the Conference Committee.) 50*s*. net.

THIS volume is one that no professional operational research worker can be without, for it gives a very wide sample of the types of problems which he may be likely to be called upon to deal with. It has already become a recognized source book in the short period since publication. Not the least valuable parts of it are the references to earlier work and the discussions, which have been kept commendably brief.

The volume may possibly leave a stronger impression than is desirable that operational research is not much more than applications of advanced mathematical and statistical methods to decision problems. On the other hand, the methodology of operational research is much more mathematical and statistical than general scientific; this conference was methodological, and so it is not surprising that the published matter exhibits apparent bias.

A weakness in industry is to think of operational research as solving problems which require these advanced methods (these are the cases which, incidentally, can usually be published without breach of confidence) and excluding the class of problems which can be resolved by much simpler techniques. An enormous amount of progress can be made with little more mathematical equipment than the elements of the theory of functions, for after all what is a business enterprise but a mathematical function when represented in a form suitable for analysis.

A curious feature of the Conference Proceedings is that almost everywhere in the world military operational research seems to be ahead of industrial work. This is understandable in countries which were involved in military operational research during 1939–45. It is, however, less understandable in other countries.

This is not a work for business executives, unless they happen to be well equipped with a knowledge of mathematics and statistics. Perhaps this is unfortunate, but after all the object of the Conference was to aid the operational research scientist, rather than the employer. It is to be hoped, however, that much more attention will in future be devoted to educating the potential customer. British industry is undoubtedly making quite insufficient use of the men available who can apply scientific methods to problems at all levels from the board room to the shop floor.

The standards of printing and layout of the book leave nothing to be desired. K. PENNYCUICK

THEORY OF ROCKET FLIGHT

Exterior Ballistics of Rockets

By Prof. Leverett Davis, Jr., James W. Follin, Jr., and Prof. Leon Blitzer. Pp. v + 457. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 64*s*.

THIS book expounds the mathematical theory of the motion of unguided rockets stabilized either by fins or by spin, and launched either from the ground or from an aircraft. After defining the force-system the authors formulate the equations of motion and solve them under the usual approximation of constant acceleration, to obtain the ideal trajectory and to show the errors arising through malalignment of thrust, the action of gravity and wind, tip-off effects as the rocket leaves the launcher, and the various other hazards which mar the accuracy of this type of missile. The book ends with a useful collection of formulæ and tables of Fresnel functions.

The theory presented in the book was developed in the United States during and just after the Second World War, but the final report on the work was not printed until 1953. Before open publication was allowed, various items had to be deleted, and the authors also made corrections and a few additions. The book has been reproduced from the 1953 report thus modified, by a photo-offset process. One beneficial result of this procedure is that there are very few misprints: so high is the standard that the mis-spelling of Jeffreys on p. 166 comes as quite a shock. The authors write well, and they develop the theory in a logical order, fully explaining the physical basis for each step in the argument. The result is a book which is unlikely to be superseded for many years. Its value is enhanced by the pleasing layout and by the clarity of the print, especially the mathematical symbols and the diagrams (though there are a few messy diagrams, one of which seems to be a freehand sketch). Many footnotes have been deleted because they refer to classified material, and the frequent gaps at the bottoms of pages are a mute memorial to the many workers whose contributions to the theory will remain generally unknown.

The long delay in the final publication of the book inevitably detracts a little from its worth. For example, the list of rockets for which design details are given has an air almost of antiquity, and it is noticeable that very few of the references are later than 1947. Also it is obvious that the book was virtually complete before the publication in 1949 of Rankin's "Theory of the Motion of Rotated and Unrotated Rockets", which indeed does not appear among the footnotes until p. 433, though it covers much of the same ground. Those who are familiar with Rankin's monograph will find that the book under review does not go so deeply into the fundamentals, and mathematically it is less rigorous; but there is a much fuller explanation of the physical processes and more linking narrative. Indeed, the authors are to be congratulated on producing a book which, as well as being authoritative, is, considering the difficulty of the subject, easy to read.

D. G. KING-HELE

PROGRESS IN CHEMICAL ENGINEERING

Advances in Chemical Engineering, Vol. 2

Edited by Thomas B. Drew and John W. Hoopes, Jr. Pp. x+338. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 9.50 dollars.

THE second volume of this work follows the same general pattern as the first (*Nature*, 179, 503; 1957) and includes chapters on six unrelated topics, some of which are of predominant interest to the chemical engineer, whereas others should command a wider range of readers. Nor are all the chapters written at the same level; some assume a considerable prior knowledge of the subject, whereas others start with the elementary concepts and are occasionally superficial in their approach. The general impression is again that most of the items would more usefully have been published as individual monographs, in order to obviate the necessity for the reader to buy much material that he does not require. In this connexion, the publishers are considerably at fault in splitting the contribution on boiling liquids between the two volumes.

The first chapter follows on naturally from the material on boiling liquids in Vol. 1, and deals particularly with transition and film boiling, on which subjects there is far less published work than on nucleate boiling. The approach is somewhat factual and uncritical. The chapter concludes with sections on localized boiling in liquid the bulk of which is below its boiling point, and on bumping, which apparently takes place only in laboratory-scale apparatus.

Automatic process control is treated from a fundamental point of view, which will be of value to the newcomer in the field. The theory of control and different types of control action are discussed, but no reference is made to the instruments which are used, nor are there any practical examples related to chemical engineering problems.

The following chapter is entitled "Treatment and Disposal of Wastes in Nuclear Chemical Technology". It includes a general discussion of disposal problems with special reference to the geological and climatic requirements of the site. Methods of concentration before disposal are considered, and the concluding section refers to the recovery of fission products.

The chapter on high-vacuum technology tends to be a little superficial. Following a historical account of the development of the subject, there is a brief account of the flow of gases at low pressures, with special reference to the transition between molecular and laminar flow. Convective heat and mass transfer at low pressures are discussed and the chapter concludes with a short description of some common types of vacuum pumps and gauges.

An extensive treatment of separation by adsorption methods is particularly welcome because of the lack of a satisfactory literature on the subject. The discussion embraces the fields of ion exchange and chromatography, and particular attention is paid to the effect of the shape of the adsorption isotherm on the process.

The final chapter on the mixing of solids covers the subject in considerable detail. The problems of sampling and the statistical significance and interpretation of analyses are taken first. Perfect mixing is effected when the probability of finding a particle of a given type is the same at all points and is equal to the proportion of particles of that type in the mixture. There is a useful treatment of Weidenbaum's and Lacey's approach to mixing as an unsteady-state diffusional problem. The various types of mixer are considered in relation to the type of motion imparted to the particles, and various applications are given.

The volume is well produced, but it deserves a more comprehensive index.

THERMODYNAMICS AND FLUIDS

Chemical Engineering Practice

Edited by Herbert W. Cremer and Trefor Davies. Vol. 4: Fluid State. Pp. vi+623+xix. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 95*s*.; 13.30 dollars.

AN important section of the work of modern chemical engineers lies in the application of thermodynamics to problems of fluid systems. This volume, the fourth in the series, is devoted to the thermodynamic properties of physical systems and to the transport properties of fluids. The first section on thermodynamics has been written by Dr. R. Strickland Constable of the Chemical Engineering Department at the Imperial College of Science and Technology, and the second section on transport by Dr. Franklin of the Atomic Energy Authority and Mr. F. H. Cass of the University of Leeds. A final and useful chapter on the measurement of process variables is by Mr. A. Pollard and Mr. T. G. Carruthers of Leeds.

The first six chapters start with a short summary of the first and second laws of thermodynamics and continue with such topics as chemical potential as a criterion for equilibrium, general thermodynamic relationships, properties of single substances and of mixtures. In many ways this is a good section. We are given an excellent account of what is sometimes called chemical engineering thermodynamics of the fluid state, and the chapter on sum and difference methods is particularly useful in providing a basis to stagewise operations as indicated by liquid–

liquid extraction and so on. The main drawback to this section is that there are scarcely any examples and few good illustrations of the use of the thermodynamic functions. It is not sufficient to give thermodynamic functions, and relations between them, these concepts only become alive when it is clearly shown that they form useful tools. The Gibbs function and the Van Laar equations must be demonstrated to the practical engineer as of real use, and effective illustrations are vital.

The second section on the transport of fluids has more examples and clearly shows the great interest in boundary layer study, in the ideas of turbulence, and the flow and behaviour of compressible fluids. Here again practice is somehow missing, and the examples are rather academic.

This is a valuable book in that it provides the current ideas of the thermodynamic approach to the study of fluids; this has previously not been so clearly available in British texts. The volume suffers from the fact that one is not given the dynamic illustrations of the use of these tools, one does not sense the engineer at work at his practice, but rather that he is being presented with an academic text. How does one really design a large pipe-line, how does one measure the flow of high-pressure and high-temperature fluids, how do engineers really solve their problems ? Some actual examples, including failures that had to be corrected, would have been of great value to the practically minded reader.

J. M. Coulson

DRUGS AND THE BRAIN

Psychotropic Drugs

Proceedings of the International Symposium on Psychotropic Drugs, Milan, May 9–11, 1957. Edited by S. Garattini and V. Ghetti. Pp. xiv+606. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1957.) 95*s*.

This expensive and extremely well-produced volume constitutes the proceedings of the International Symposium on Psychotropic Drugs held in Milan during May 9–11, 1957. It was printed in the Netherlands, and editors and printers deserve much praise for the speed with which the work was done and the excellence of the result; it cannot have been an easy task to assemble the final versions of the papers and to set the text in four different languages.

There are approximately 100 reports, roughly half of them quite short, the others of variable length. These reports are grouped into five sections, dealing with the biochemistry of normal and altered cerebral function, the behavioural effects of psychotropic drugs on animals, the electrophysiological basis of normal and altered cerebral function, the pharmacological aspects of centrally acting substances, and lastly clinical experiences. The drugs most widely used in the studies reported are the so-called tranquillizing drugs, in particular reserpine and chlorpromazine; hallucinogens are also well represented, and there are, of course, studies of the more traditional stimulant and depressant drugs as well.

The reader of this book will be impressed by a number of things. In the first place, there is a tremendous range in the simple technical competence of the research workers represented. This expresses itself in many different ways. To take but one example, we find that the psychologists tend to report means and variances for their experiments; the biochemists tend to state means only; the clinicians tend to rest content with a simple subjective estimate of trends. As the numbers used are normally quite small, and the variability in response to drugs is known to be tremendous, it is clear that for a number of reports no conclusions can be drawn from the figures given, because vital information is withheld and no tests of significance carried out. A second impression relates to the relative isolation of the various groups of workers. Any adequate theory of drug action must surely reconcile and synthesize the findings of biochemists, psychologists, pharmacologists, physiologists and other workers, yet each group tends to remain isolated from the others and ignorant of what is being done elsewhere. Perhaps the series of congresses, of which this was the first, may have the highly desirable effect of bringing these various workers closer together.

Some of the contributions are of such high quality or of such obvious interest that they stand out from the rest. Among them is a paper by A. Hoffer on the relation to mental disease of adrenochrome and adrenolutin; this investigation owes its interest to the similarity in the structure of these two oxidized derivatives of epinephrine to some active indolic hallucinogens. Another is a paper by N. E. Miller on objective techniques for studying motivational effects of drugs on animals; this combines in a remarkable manner a survey of available techniques with an exposition of the writer's own work; it is a gold-mine of information, as well as an admirable presentation of recent methodological advances in this field. B. Delisle Burns, in his paper on the electrophysiological basis of normal and psychotic function, discusses the bearing of his recent work on the physiology of learning, suggesting that traditional hypotheses of facilitation are erroneous. J. Olds and others contribute a chapter on the effects of tranquillizers on self-stimulation of the brain in which the remarkable discoveries of Olds on the rewarding properties of electrical stimulation of certain brain areas are used to discover the effects of a variety of drugs. His main discovery is the highly specific action of most drugs, depending on the precise placement of the electrodes. These are only some of the noteworthy contributions to this volume; others could have been mentioned as well. While having the inevitable defects of any symposium, this collection of papers has succeeded surprisingly well in presenting the reader with a worthwhile prospectus of current work.

H. J. Eysenck

MICROBES AND THE BIOCHEMIST

Annual Review of Microbiology

Vol. 11. Edited by Charles E. Clifton, in association with Sidney Raffel and Roger Y. Stanier. Pp. viii+536. (Palo Alto, Calif.: Annual Reviews, Inc., 1957.) 7 dollars.

The time is long past when biochemistry of micro-organisms could be covered adequately by a chapter in the "Annual Review of Biochemistry". To-day we have the converse situation, and the microbiology volume has an established place in the biochemist's library. Reviews such as Gale and McQuillen's on nitrogen metabolism might even prove heavy reading for many biochemists; though anyone wishing to understand some of the most exciting biochemical research of to-day will find this a most rewarding chapter. More than half the articles in this volume have a directly biochemical outlook, but in few can the reader escape far from fundamental biological observations which are unlikely to be interpreted at the molecular level for a very long time to come. This volume, indeed, provides a salutary warning against the facile assumption of biochemical omnipotence. This is apparent, for example, in Smith's essay on "Some Problems in Plant Virus Studies", which leaves the reader wondering whether viruses may not sometimes arise *de novo* in a healthy cell. Smith himself hastens to disclaim this heresy ; but at least this kind of patient observation and research provides a needed corrective to the over-enthusiastic bacteriophage specialist. It is, however, a matter of great practical importance to know whether the remarkable biochemical observations made on bacteriophages in recent years are valid for animal viruses and, in particular, human pathogens. Ross and Syverton, in their review on the culture of animal viruses in cell-suspensions, raise legitimate hopes that experimental study of their biochemical behaviour may be feasible.

We are led right back to the practical plane of field observations when we come to Miller and O'Brien's review on "Prediction of Plant Disease Epidemics", and the microbiologist finds himself allied with the meteorologist rather than the biochemist. This review will prove of great value to workers on this topic. Not only are scattered data collected from inaccessible journals, but a challenge is thrown out to the academic worker, too. Why should a parasitic fungus attack its host only when certain conditions of temperature and humidity are fulfilled ? One wonders if equally well-documented data are available for human diseases. But as "Annual Reviews" reveals new knowledge it also reminds us of territory where progress is less evident. One reads Thornton and Mieklejohn's contribution on "Soil Microbiology" with a sense of disappointment. In a world the human population of which is threatening to outgrow its food supplies, surely a greater effort could be directed to study of those micro-organisms which maintain the fertility of the soil—not only by circulating supplies of vital elements, but also through their influence on the very structure of the soil itself. Dental caries, too, is an expensive as well as a painful disorder, yet Hoffman's review on oral microbiology (though collecting much useful information for the bacteriologist's file) offers little hope for the victim of toothache.

One reads this volume with a sense of pleasure. It is all too easy for chapters to degenerate into undigested catalogues of references. This charge cannot be made here. Many of these articles are reviews in the best sense—presentations of the trend of current work by an acknowledged authority and in a form acceptable to those at the fringe as well as the centre of his chosen sphere. Many authors have wisely preferred to select topics which present interesting developments at the present time rather than to attempt to cover the literature comprehensively. But where the topic has been one of essentially specialist interest and it has been necessary to collect scattered references, this has been done faithfully. This volume has to meet a wide range of needs—from those of the academic biochemist to the clinical pathologist's or the agricultural field worker's. Editors and authors alike have served their readers well.

H. K. King

TAXONOMY OF VASCULAR PLANTS

Plant Classification

By Prof. Lyman Benson. Pp. xiv+688. (Boston, Mass.: D. C. Heath and Company; London: George G. Harrap and Co., Ltd., 1957.) 63*s*.

Prof. Benson, well known for his studies on *Ranunculus*, has produced a text-book dealing primarily with the classification of vascular plants but covering, at least in outline, a very considerably wider field.

The methods of collecting, preserving and describing plants, most of them at least 250 years old but still basic tools of taxonomy, are put into perspective alongside more recently developed parts of the field, such as ecology and genetics. This in itself should make the book of special value both to those whose interest is primarily in the classification of organisms and to the ecologist or geneticist.

The introductory chapters are concerned with the characteristics of flowering plants, the terms used in describing them, and the process of identification by means of keys. These, like the rest of the book, are abundantly illustrated by diagrams and line drawings, and the way to use a key is explained in detail by reference to species of *Ranunculus*. This part, most of which is in effect a detailed illustrated glossary, will be specially useful to the beginner.

The next 270 pages contain keys to the orders and families of flowering plants, brief descriptions of the families with a summary of their distribution, with special reference (naturally enough) to the United States, and sometimes a note on the geological history. This survey is on a world scale, though the descriptions appear usually to apply to the family as represented in the United States, a fact which, unfortunately, does not seem to be made clear. The result is that we are told, for example, that the Leguminosae are "Predominantly herbs but frequently shrubs and less commonly trees", a statement which is true for the United States, but quite untrue for the Leguminosae as a whole.

The chapter on the preparation and preservation of plant specimens deals with an aspect of the subject which is usually learnt by experience, but in which some instruction will save time and lead to better results.

The comprehensive section on the basis of classification consists of an outline, in 84 pages, of many topics which are of great importance in taxonomy but which have seldom, if ever, previously been included in text-books of this kind. There are chapters on evolution, examples being drawn from animals as well as plants, some fundamental problems of plant classification, historical development of classification systems and a system of classification designed for teaching.

The chapter on fundamental problems includes much valuable material, such as a brief consideration of hybrid swarms and convergent and divergent evolution, each topic being exemplified by reference to the flora of the United States. The final chapter of this section has a somewhat misleading title ; it consists of a discussion of the desirability and difficulty of producing a new classification, a summary of the evidence on which a phylogenetic one might be based, and a defence of the employment of a partially artificial system for teaching, as the

'Ariadne's thread' by means of which the student can be guided through the great mass of facts.

The book concludes with shorter sections, similar in general plan, on Gymnospermae and Pteridophyta, and a survey of the main vegetation types of the United States illustrated by excellent photographs and distribution maps.

Altogether this is a book admirable in conception but only partially suited to the student at an English university. There is the inevitable drawback that the examples quoted are familiar in the United States but only rarely so in Europe. A more fundamental difficulty is, however, that a good deal of space is occupied by material which is of General Certificate standard and that the rest of the subject-matter is too extensive for a general honours student but not carried to high enough levels, at least in the large and variable families, for the special honours student. Nevertheless there is no doubt that students of all grades, as well as their teachers, will gain much from browsing through this work. T. G. TUTIN

THE LIVING INVERTEBRATE

Spiders, Scorpions, Centipedes and Mites

The Ecology and Natural History of Woodlice, 'Myriapods' and Arachnids. By Dr. J. L. Cloudsley-Thompson. Pp. xiv+228+16 plates. (London and New York: Pergamon Press, 1958.) 50*s*. net.

THE author of this book is well known as a zoologist who has a predilection for seeking his living material in deserts and other uncomfortable places, where the frequent changes of temperature, illumination and humidity have pronounced effects on the lives of invertebrate animals, and he has supplemented this field-work with a long series of laboratory investigations on humidity preferences, water-content control and rhythmic behaviour. These researches have directed his attention to those arthropods which are not insects and which are very well suited to his purposes. The zoologist, the naturalist and the general reader are far less familiar with these animals—the woodlice, myriapods and arachnids—than with insects, and all will find a wealth of interesting matter in this book. By his introductory chapter, in which the first figure is a graph illustrating problems of desiccation, the author makes it plain that he does not intend to popularize or oversimplify his subject; and this attitude, none too common in books about animals, is consistently maintained and gives the book its outstanding characteristic. It is a feature that will commend itself to many zoologists, both readers and writers, and will even be a pleasant surprise to others.

The eleven chapters follow closely parallel lines. For each order or other grouping we are told of classification and distribution, general behaviour, food and enemies, reproductive habits and life-cycle. These topics are periodically lightened by the introduction of less-technical paragraphs. The author is always ready to remind us of myths or legends which have centred about these creatures and to share with us the smiles that they have sometimes provoked. With all his exact knowledge of recent work—and I have failed to find any topic of importance that has been omitted—he gives credit to the observers of past generations, who often hit upon facts or phenomena of significance and who, even if they did not fully understand them, have left us descriptions or illustrations which are still useful.

There is a section of excellent half-tone plates, but the supply of line figures is not over-generous. For example, there are references to the uses of pedipalpi and gnathobases where an uninformed reader might expect a drawing to make the text clearer.

None the less, this is a book of uncommon quality, and a first-rate example of zoological writing adapted to the widening reading public of the mid-twentieth century. Accurate without being abstruse, appreciative without being sentimental, clear in interpretation where interpretation is possible and as clearly conscious of difficulties where they exist, it should be welcomed by many. Perhaps it heralds a new movement in biology—a directing of popular attention to the unspectacular orders, from which so much is to be learnt. In this venture Dr. Cloudsley-Thompson must be congratulated; and a word of commendation is due to the publishers, who have shown faith and courage in producing so challenging a book. THEODORE SAVORY

OUR NATIVE MAMMALS

Field Guide to British Deer

Compiled and edited by F. J. Taylor Page. (Field Guide to British Mammals, No. 1.) Pp. 80. (Birmingham: Mammal Society of the British Isles, c/o the University, 1957.) 10*s*. 6*d*. net.

The Natural History of the Otter

By Marie N. Stephens. (A Report to the Otter Committee.) Pp. 88+4 plates. (London: Universities Federation for Animal Welfare, 1957.) 10*s*. 6*d*.

The Badger

By Ernest Neal. (Pelican Book No. A 410.) Pp. 176+30 plates. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1958.) 3*s*. 6*d*.

THE first impression one gains from reading these three books is of the greatly increased interest now being taken in the natural history of our native mammals. The very formation of the Mammal Society of the British Isles a few years ago was evidence of that interest, and the publication of the first of its planned series of field guides, noted above, is a welcome addition to our literature on British deer. It deals chiefly with the five species most commonly found at large in Great Britain, but contains notes also on other species, such as the Chinese waterdeer, which may be seen in very limited areas.

This "Field Guide to British Deer" is a model of clarity and compactness. In its mere eighty pages it contains a wealth of observations, tables and sketches that one is unlikely to find in any other British book, all carefully compiled and set out to help one to ascertain which deer are present in any particular region, and to identify them when seen. Distribution, habitat, gait, tracks, droppings, seasonal behaviour, daily activities, voice, antlers, food and so on are all dealt with in a way that makes this attractive little book in green and gold a pleasure to consult. One looks forward eagerly to its promised successors in the same series.

So far as naturalists are concerned, the chief interest of "The Natural History of the Otter" will lie in Miss Stephens's intensive studies of this elusive animal in its natural haunts. The details she gives of its distribution and habits, its reproduction and breeding behaviour, its parasites and diseases, and above all its feeding habits, cover much fresh ground, and will throw new light on many an old belief regarding the otter's relationship to man and his needs.

These investigations were, in fact, carried out as a result of the report issued by the Home Office Committee on Cruelty to Wild Animals, which appeared in 1951. This Committee concluded that, since the hunting and trapping of otters undoubtedly involves suffering for these animals, a thorough investigation should be conducted into the natural history of the otter, and particularly into its feeding habits, so that an informed judgment could be arrived at concerning its alleged damage to fishing interests. It is unfortunate that, through lack of funds, the work had to be discontinued after about two years. It will be agreed, however, that an excellent start has been made, and one can only hope that such an interesting and useful project will be revived at no distant date.

The appearance of Ernest Neal's "The Badger" as a paperback will be welcomed by all who missed the original edition, which was published ten years ago as a New Naturalist Monograph. It is a magnificent example of well-directed endeavour, untiring patience and skilled photography, and now provides, as inexpensively as anyone could wish, a first-class introduction to the natural history of one of the most interesting of our lesser-known mammals.

RICHARD MORSE

AGE AND ABILITY

Ageing and Human Skill

A Report centred on work by the Nuffield Unit for Research into Problems of Ageing. By A. T. Welford. Pp. ix+300. (London: Oxford University Press, 1958. Published for the Trustees of the Nuffield Foundation.) 25*s.* net.

FOR ten years from 1946 until 1956 the Nuffield Foundation supported a Unit for Research into Problems of Ageing attached to the Cambridge University Psychological Laboratory. The present volume is the final and definitive account of the work accomplished by the Unit during this period, and in view of the high reputation which Mr. Welford and his team won for themselves it will be eagerly read not only by psychologists and gerontologists, but also by all who are interested both theoretically and practically in human performance. They will not be disappointed. In an eminently readable book Mr. Welford has made an outstanding contribution at once to the study of ageing and to general psychology.

The book is a successor to, and intended to supersede, Mr. Welford's earlier report "Skill and Age" (1951). It is just twice the length of the previous book; and although it contains again in new contexts most of the earlier material, it also contains much additional data and a re-working of the theoretical framework. It is richer in reflexions and suggestions for future work, refers to relevant research by other investigators, and includes a valuable new chapter on methodological problems in the study of ageing. On the other hand, the statistical appendix provided in the earlier volume has been omitted, and in an endeavour to simplify the statistical presentation rather too much vital information has been left out. For example, not until more than half-way through the book, and then only sporadically, are the numbers of experimental subjects given. As not all the experiments have been separately reported, it becomes impossible for the reader to carry out an independent evaluation of the results, and he has to accept the author's blanket statement that all the results are in fact significant at the 5 per cent level or better.

Broadly speaking the conclusions of "Skill and Age" are confirmed and amplified by "Ageing and Human Skill". Perhaps the most important additional finding from the practical point of view is the conclusion derived from the work of Kay and confirmed by other investigators that "changes of performance with age very commonly become disproportionately greater as the difficulty of the task rises". In an extremely interesting experiment on the training of women engaged on invisible mending in factories making woollen cloth, Belbin, reported here for the first time, has shown how a simplification in the way material is presented can profoundly affect the likelihood of success for trainees in middle age and beyond. This is one of a number of new industrial field studies reported in the book.

The re-working of the theoretical framework has led to the introduction of several new features. In "Skill and Age" skilled processes were analysed into receptor processes and effector processes. Between these is now included a third type of process, translation processes, which intervene between perception and action. Experimental examples are given illustrating the translation processes involved in transposing from one sensory mode to another and in making mirror reversals, but it cannot be said that Mr. Welford has made the scope and nature of these translation processes at all clear, nor has he made any attempt to explore their relationship to symbolic functioning generally. Theoretically their status remains vague. Perhaps more important is the new emphasis on the role of short-term memory backed up by a good deal of recent experimental work. Mr. Welford suggests that short-term retention is increasingly liable to interference by other activity as age advances, and that a good many of the diverse facts about learning and other changes of performance with age can be accounted for in this way. A possible explanation, he holds, may be contained in the fact that the number of active brain cells tends to diminish from young adulthood onwards, thus leading to a lessening of signal strengths, a lowered capacity for the establishment of reverberant circuits (upon which short-term retention probably depends), and a consequent increase of relative 'noise' level.

Inevitably in a book which covers a wide range of topics—movement, perception, problem solving, learning and memory, adaptability, etc.—there is some unevenness of treatment. The book is strong on the motor and perceptual aspects of skill. It is relatively thin and unsatisfying on problem solving and learning. The emotional, attitudinal and social factors which influence performance receive scarcely more than mention. But it would be unfair to hold these omissions against Mr. Welford, and only fair to point out that he is fully alive to them. With a small team of assistants, and in a limited period of time, he staked out his claim and has produced an impressive yield of results. Indeed, there is little doubt that the research reported in this book will be judged as one of the most significant pieces of psychological work produced in Great Britain since the Second World War.

organic chemical reagents

Hopkin and Williams Ltd. have been noted, for many years, for their range of Organic Reagents for the detection or determination of metals, and other radicals, and the Company is publishing, regularly, a series of Monographs relating to these reagents.

The following Monographs are available free on request:—

No. 34 CARMINE—Reagent for Boron.

No. 35 2:4-XYLENOL—Reagent for Nitrate.

No. 36 *p*-BROMOMANDELIC ACID
—Reagent for Zirconium.

Previous Monographs in the series have already been issued in collective form, under the title "Organic Reagents for Metals, and Other Reagent Monographs", Volume 1. Copies of this publication are still available at 15/- nett, post free, and full details will be sent on request.

Soviet Research in Glass and Ceramics

Basic Science I. Pp. 1–259. Basic Science II. Pp. 260–497. 90 dollars. Glass, Glazes and Enamels. Pp. 197. 40 dollars. Cements, Limes and Plasters. Pp. 203. 35 dollars. Refractories. Pp. 70. 20 dollars. Miscellaneous. Pp. 31. 7.50 dollars. (New York: Consultants Bureau, Inc.)

THE Consultants Bureau, Inc., New York, have prepared translations of recent publications in Soviet research in glass and ceramics. These are available in five mimeograph collections. Full contents lists are available from Consultants Bureau, Inc., and individual reports can be purchased for 7.50 dollars each. It is useful to have in a form so easily available these translations of Russian publications. A very brief indication of the nature of the topics discussed may be given by referring to two major subjects on which several papers are included.

There are several papers on solid-state reactions by Ginstling and co-workers; these reactions are considered under the following headings: Chemical Reaction; Diffusion; Sublimation; Fusion; Crystallization.

Apen, in a lengthy series of papers, discusses the structure of silicate glasses in the light of the trend of behaviour of glasses as the composition is varied systematically. This information, together with the known co-ordination numbers of the various ions in crystals, is used to discuss the co-ordination of those ions in glasses.

There are many technological papers dealing with the reaction between sodium sulphate, carbon and silica, the thermal analysis of limestone, magnesite and dolomite in gas streams, the reaction of glasses with water and hydrofluoric acid, to mention only a few.

Of rather more general interest is a paper on X-ray transmitting glasses (Lindemann glass) with improved chemical durability. R. W. Douglas

Linear Equations

By P. M. Cohn. (Library of Mathematics.) Pp. viii+74. (London: Routledge and Kegan Paul, Ltd., 1958.) 5*s*. net.

Sequences and Series

By J. A. Green. (Library of Mathematics.) Pp. viii+56. (London: Routledge and Kegan Paul, Ltd., 1958.) 5*s*. net.

Differential Calculus

By P. J. Hilton. (Library of Mathematics.) Pp. vii+56. (London: Routledge and Kegan Paul, Ltd., 1958.) 5*s*. net.

Elementary Differential Equations and Operators

By G. E. H. Reuter. (Library of Mathematics.) Pp. viii+67. (London: Routledge and Kegan Paul, Ltd., 1958.) 5*s*. net.

THESE booklets, by members of the mathematics department of the University of Manchester, are intended for the student of science or engineering; they are in paper covers, but are well printed and reasonably cheap. The scope of Cohn's book is wider than the title, since linear equations are used to link together basic ideas about vectors, matrices and determinants. The discussion of m equations in n unknowns is carefully carried out, and a numerical method of solution is described.

Green's book treats sequences and their limits rather narrowly as a preliminary to the theory of series. The frightening professional apparatus of modulus signs and epsilons is discarded, and formal proofs are replaced by careful descriptions and apt numerical examples. The main convergence tests for series are given, including the integral test, and the properties of power series are given in some detail.

Hilton aims at comprehension rather than facile manipulation. The student must understand the meaning of the derivative; if correct proofs are too difficult, he must not be deceived by bogus arguments or false statements. Applications are to maxima and minima, and Taylor's theorem; the proof of the latter is a little too sophisticated for the science student, usually too ready to believe that mathematics is largely trickery.

Reuter is concerned with linear differential equations with constant coefficients. He first gives the familiar D method, and then an operational method which takes care of initial conditions; this is essentially Heaviside, and Reuter's treatment is on the lines of that given in the Cambridge tract by Sir Harold Jeffreys.

These are all useful little books, and topics suitable for similar treatment are doubtless under consideration by the editor of the series, Dr. Ledermann.

T. A. A. Broadbent

Advances in Biological and Medical Physics

Vol. 5. Edited by John H. Lawrence and Cornelius A. Tobias. Pp. x+488. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 12 dollars.

THE latest volume of this series contains an excellent selection of review articles taken from various parts of the subjects of medical and biological physics, together with a few excursions into subjects which can scarcely be regarded as 'physics', although no doubt they are of interest both as tools and as subjects for future biophysical researches. T. T. Puck's article on the genetics of somatic mammalian cells comes mainly within this category, although it includes some account of the action of high-energy radiation cells when grown under tissue culture conditions. The remaining articles cover a wide range of physical approaches to biological phenomena, for example, paramagnetic resonance, action spectroscopy, dielectric properties and even television techniques in biology and medicine.

Other articles deal with methods of low-level counting of radioactive isotopes (Anderson and Libby), which have assumed world-wide importance in view of the increasing contamination of the atmosphere, and the radioactivity of the human body (Spiers and Burch), an equally important subject at the present time.

W. F. Bale and J. L. Spar discuss the use of antibodies as carriers of radioactivity for therapy. This is an interesting idea, but I do not think the authors have quite established their case that (with isolated exceptions) the therapy of specific organs is a practical proposition at present. Still, it is of much interest to have a review of the experiments made in this direction.

A. Rose gives a discussion of some rather special features of human vision and R. E. Zirkle, in an excellent article, discusses the methods developed in his laboratory for the irradiation of small parts of cells and the effects observed so far.

J. A. V. Butler

^{14}C-PROLINE AND HYDROXYPROLINE IN THE PROTEIN METABOLISM OF PLANTS

AN EPISODE IN THE RELATION OF METABOLISM TO CELL GROWTH AND MORPHOGENESIS

By Prof. F. C. STEWARD, F.R.S., and Dr. J. K. POLLARD
Botany Department, Cornell University, Ithaca, New York

PLANTS have the distinctive ability to synthesize protein from sugar and inorganic sources of nitrogen, and in this nitrogen-autotrophic behaviour they contrast sharply with the nitrogen-heterotrophic nutrition of animals. In fact, this ability of growing plants to carry out what may be called primary protein synthesis, that is, a net synthesis of protein from inorganic materials, represents one of the great outstanding biological problems. However, the association, if not the causal connexion, between protein synthesis and the growth of cells by division and by cell enlargement needs no re-emphasis here.

Plant proteins rarely contain hydroxy-L-proline in the quantities encountered in the collagen-like materials of the animal body. Indeed, hydroxyproline does not occur free in quantity in plants except in certain exceptional situations, and even then it may not be in the form (hydroxy-L-proline) that exists in collagen or in protein (for example, allo-hydroxyproline in *Santallum*[1]). Particular interest, therefore, is attached to some examples in plants in which ^{14}C-proline is directly and rapidly incorporated into a metabolically inactive plant protein (insoluble in alcohol, precipitable with trichloracetic acid), and then is progressively converted to bound hydroxy-L-proline.

The new observations to be described have developed out of an earlier investigation which was summarized in *Nature* and has been published more fully in the *Journal of Experimental Botany*[2]. The features of the new work which bear upon the subject of protein synthesis and which are of more general and current interest will now be summarized.

Hydroxyproline in Plant Protein

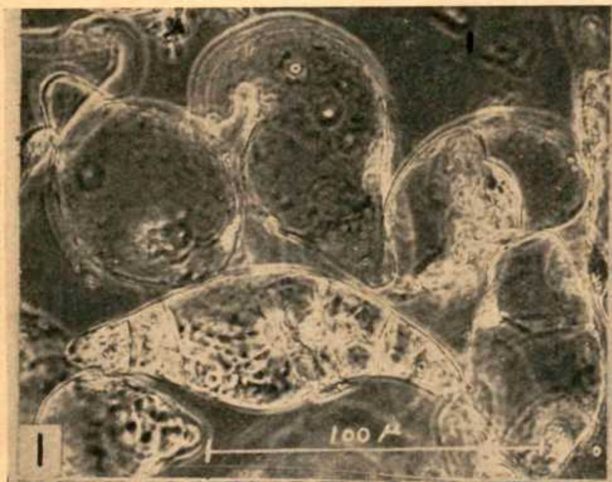
Hydroxy-L-proline is unusually conspicuous in the hydrolysates of the total protein of plant cells which are active in random proliferation. This has now been shown for carrot tissue cultures grown on a medium which contains coconut milk, for potato tissue cultures grown on a medium containing coconut milk and 2,4-D (2,4-dichlorophenoxyacetic acid) or some equivalent substance, for tumours which grow on *Nicotiana* hybrids, by virtue of their genetic constitution, and for the tumours which grow on *Kalanchöe* by the effect of the crown gall organism[3]. Hydroxy-L-proline occurs in substantial amounts in the protein hydrolysate of all these systems, even to some extent in the tissue which is formed by wound healing in the potato tuber, whereas it is either absent from, or present only in small amount in, the normal tissue. These observations should have meaning in the interpretation of the rapid proliferation which is characteristic of tumorous growth. It is also significant that tissue embarking upon this rapid proliferative growth can incorporate ^{14}C-proline readily into its protein and then convert it to hydroxy-L-proline.

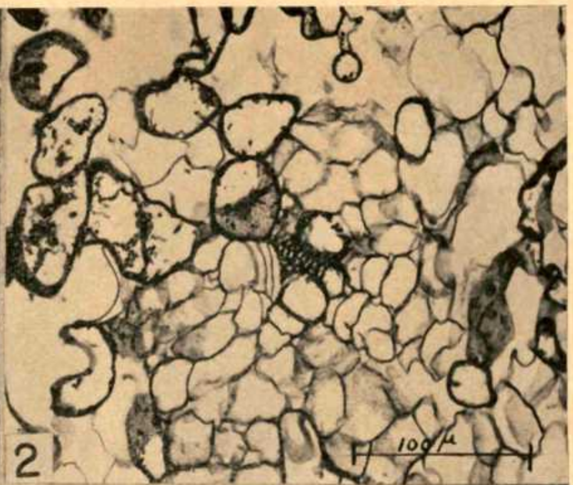
Growth of Disassociated Carrot Cells : Development from Carrot Cells to Carrot Plants

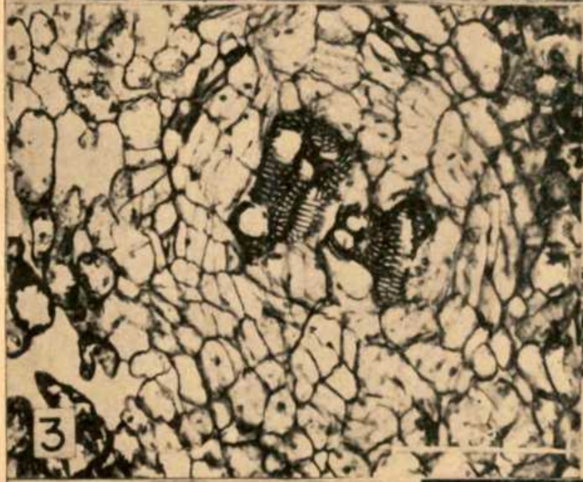
More recent evidence in this laboratory now shows that carrot phloem cells may be grown in the disassociated state in a culture medium which contains coconut milk (Fig. 1), and, after many transfers from culture to culture in this way, cells will re-form a loose proliferated mass (Figs. 2, 3 and 4), within which nodule-like centres of organized growth develop (Figs. 3 and 4). Cells in direct access to the coconut milk stimuli continue in random proliferation, but organized development only occurs after a more orderly type of growth develops. This orderly growth is stimulated by differentiating cells, around which a spherical sheath of cambial-like tissue grows in a response like wound-healing (Fig. 3). In this way a spherical nodule, or nest, of growing cells is produced within the loose tissue-cultured mass. The growing cells of this more orderly tissue now have more controlled, or limited, access to the coconut milk stimuli. It is in these situations that nests, or nodules, of growing cells have been shown to behave like the zygote, in the sense that they will form first roots (Fig. 4), then shoots (Fig. 6), and finally entire carrot plants (Figs. 5, 6 and 7) with secondarily thickened storage organs (Fig. 7). In other words, the journey from disassociated vegetative carrot cells to carrot plants has been achieved without benefit of sexual reproduction.

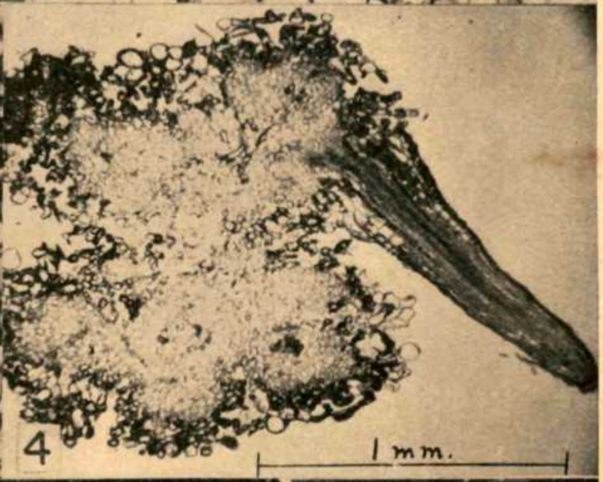
These facts of cell growth and morphogenesis are to be published more fully in the *American Journal of Botany* by one of us (F. C. S.) with M. Mapes, from whose photographs Figs. 1–7 are taken. They are mentioned here to emphasize the far-reaching conclusions that may well flow from the full understanding of all the events which first cause relatively mature cells, as they are removed from the plant body, to enter upon the rapidly proliferating state. After such cells have been grown in the disassociated state and then allowed to form colonies, they can respond to nutritional stimuli and form whole, and apparently normal, plants.

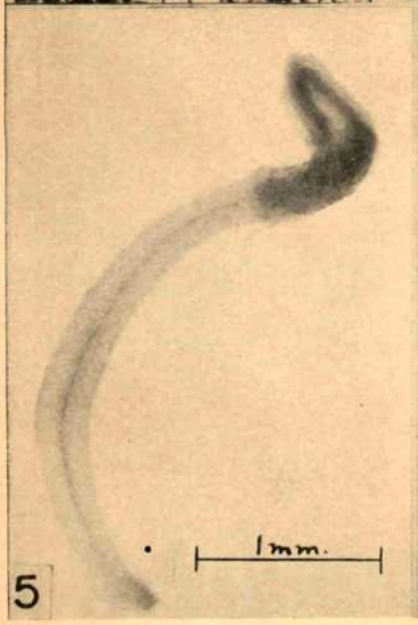
The distinctive protein metabolism of the cells which undergo the initial proliferative growth provides the background for any further changes which occur as such cells grow and form the pro-embryo-like structures. Since these events can occur, without the stimulus of sexual reproduction, when cells from mature tissue are subjected to a nutrient fluid which normally nourishes an immature embryo (namely, coconut milk or the liquid endosperm of the coconut), special interest is therefore attached to the metabolism of the cell and of the tissue cultures so stimulated. Indeed, these observations raise the question how far the events of embryology in the ovule are determined by nutrition and how far they presuppose the fertilization process. Plants in which

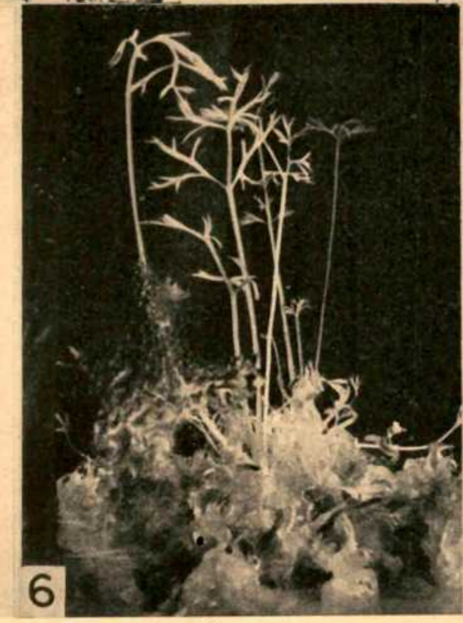


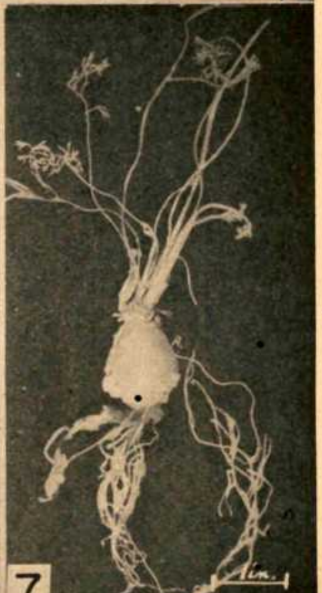












(1) A representative group of cells derived from the secondary phloem of carrot root, as these are grown in the freely suspended state in media containing coconut milk. These cells show recent divisions and a giant cell with internal divisions

(2) Loose mass formed by proliferation from cells freely suspended in liquid media; showing central cell which differentiates and adjacent cell divisions

(3) Nodule of growing cambial-like cells surrounding central nest of lignifying cells: from this structure roots and shoots develop

(4) Culture with various nodules or growing centres, from one of which a root has emerged; the roots were formed in liquid culture

(5) Young plantlet removed from loose cultured mass: shoots form only in stationary cultures on agar. This plantlet resembles an early stage of normal embryology

(6) Loose proliferated culture grown from disassociated, freely suspended, cells; roots and shoots developed as shown in (4) and (5)

(7) Complete carrot plant with shoot, root, and secondarily thickened storage organ: grown after cultures developed from freely suspended cells have been transferred to stationary semi-solid medium containing coconut milk. The storage root has proliferated where it was in contact with the medium

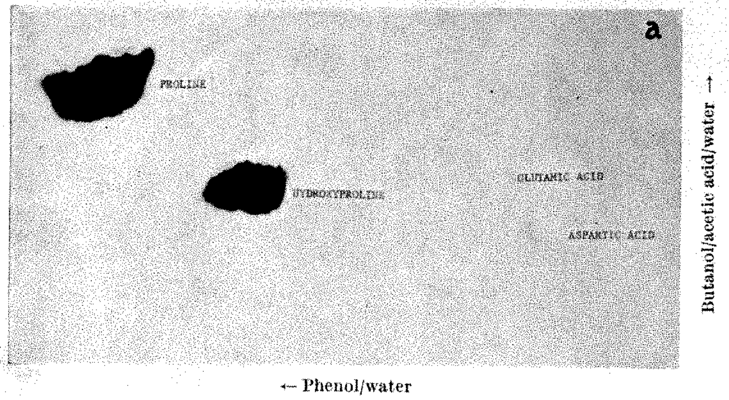


Fig. 8*a*. Radioautograph of chromatograms of hydrolysed protein fraction of growing carrot explants showing that ^{14}C-proline and ^{14}C-hydroxyproline in the protein are not metabolized

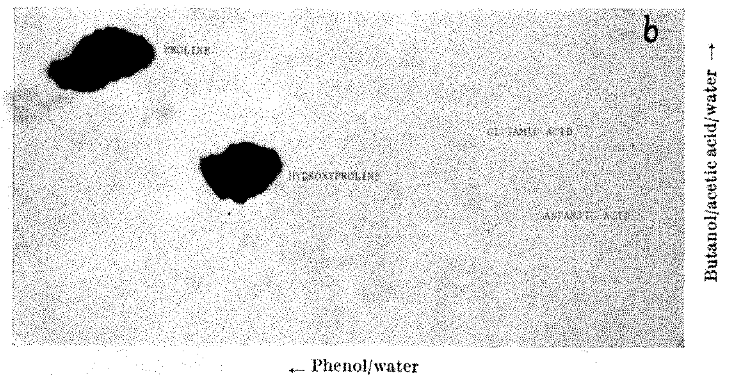

Fig. 8*b*. Tissue treated for three days with ^{14}C-proline and then grown for eight more days in ^{14}C-free media. (Average weight per explant, 72 mgm.)

apomictic development occurs may be instructive ones to investigate in this connexion.

Direct Incorporation of Endogenous Proline into Non-metabolized Protein

The role of proline in the protein synthesis of carrot tissue cultures was anticipated from work in which the protein was labelled with carbon-14 by supplying various substrates in the external medium[2]. The specific activity of the carbon in certain of the amino-acids (glutamic, aspartic, threonine) from the protein was higher than that of the corresponding free amino-acids in the cell, indicating that the carbon which became incorporated into these acids of the protein came more immediately from the carbon-14 substrate supplied than from the same acid as it occurred free in the cell. The coconut milk also increased the incorporation of carbon-14 into those amino-acids of the protein—over and above its effect upon synthesis—an effect which could only be explained by a stimulus of the coconut milk to protein turn-over, as well as its effect upon initial synthesis. The situation with respect to proline and hydroxyproline in the protein was, however, quite different from that which relates to glutamic and aspartic acids, threonine, etc. The specific activity of the proline and hydroxyproline in the protein was related closely to that of the carbon-14 in the proline free in the cell, and the incorporation of the labelled acid in the protein was stimulated by coconut milk in the same ratio that it stimulated total protein synthesis. This showed that carbon-14 could be directly incorporated into the protein from the free proline of the cell, and thenceforward it did not participate in further metabolic turn-over. This association (in growing carrot cells) of hydroxyproline with a protein moiety that does not participate in metabolic turn-over was, in this sense, reminiscent of the behaviour of collagen in the animal body.

Utilization of Exogenous ^{14}C-Proline by Carrot Explants

Against this background of knowledge, the following types of experiments have recently been performed and are to be described later in more detail[4].

Generally labelled ^{14}C-proline has been added to the external medium in which cultured carrot explants had already reached the exponential phase of their growth (that is, after several days of pre-growth in the medium). The ^{14}C-proline then rapidly enters the cell and within 15 min. radioactivity can be found in the fraction insoluble in alcohol. On hydrolysis of the fraction insoluble in alcohol, the radioactivity appears almost entirely in the form of proline and hydroxyproline, and after cultures have been in contact with the carbon-14 substrate for a day, the activity was almost evenly divided between the proline and the hydroxyproline of the protein.

Tissue which had thus incorporated ^{14}C-proline into its protein was allowed to metabolize and grow in a medium without the ^{14}C-proline for a further seven days, when it increased in fresh weight to more than 300 per cent of the initial weight; but, even so, the carbon-14 label remained exclusively in the proline and hydroxyproline of the protein (Fig. 8), and virtually none of the originally bound activity came off as carbon-14 dioxide. These facts clearly show that the protein moiety which incorporates carbon-14 directly from proline, and in which it is converted partially to hydroxyproline, certainly does not participate in metabolic turn-over. In this respect this metabolically inactive type of protein contrasts sharply with that which preferentially, but more slowly, incorporates carbon-14 from sugar into the combined glutamic and other protein amino-acids, for this protein does turn its carbon over, and some is respired away.

Conversion to Hydroxyproline

Time studies showed that the ratio of the carbon-14 in the combined proline to the carbon-14 in the combined hydroxyproline declined progressively with time—rapidly at first from a maximum of about 4 at 30 min., and thereafter slowly to a final value of 0·7 at the end of a week. In this respect the behaviour of the carrot cells is similar to that of animal cells, which synthesize collagen, for they also appear to incorporate proline and oxidize it in the protein *in situ*[5].

Time studies also showed that the direct incorporation of ^{14}C-proline into the protein of the rapidly growing cells was detectable 15 min. after its addition to the external solution, and synthesis proceeded linearly with time for some 24 hr. at least (Fig. 9).

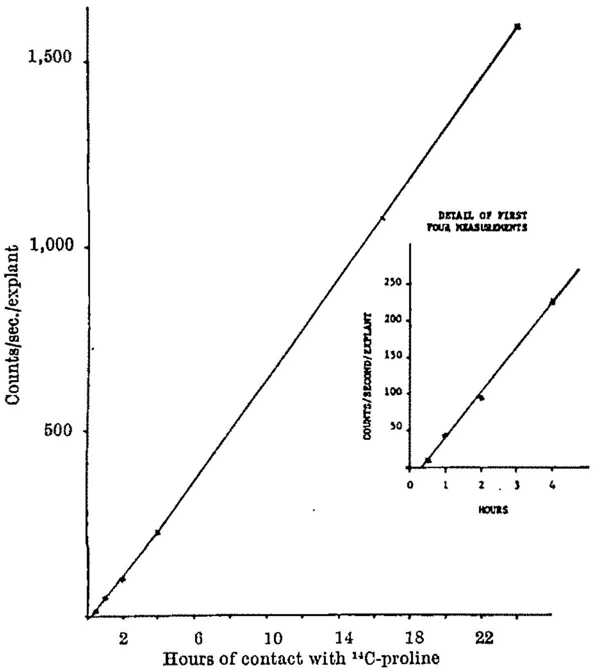

Fig. 9. Effect of time on the incorporation of carbon-14 from ^{14}C-proline into the alcohol-insoluble nitrogen fraction of carrot tissue cultures

Hydroxyproline and its Analogues as Proline Antagonists of Growth and Synthesis

Recognizing that a salient feature of the rapidly proliferating carrot cells is their formation of a protein moiety which contains hydroxyproline derived from proline, the use of exogenous hydroxyproline as a potential substrate for protein synthesis was tested. The addition of hydroxy-L-proline to the external culture solution at concentrations so low as 10 p.p.m. inhibited the growth induction, and therefore the total protein synthesis, otherwise stimulated by the coconut milk. This effect of hydroxyproline could be reversed by casein hydrolysate, but the only protein amino-acid which could do this successfully was proline itself[6]. Therefore, hydroxy-L-proline now emerges as a powerful antagonist of the growth induction due to coconut milk in this type of cell.

In co-operation with Dr. B. Witkop's laboratory in the National Institutes of Health at Bethesda, Maryland, about seventy-five compounds have now been tested for their ability to suppress growth and protein synthesis in ways that are reversible by proline[6]. The results are briefly as follows. The most effective proline antagonist is hydroxy-L-proline; hydroxy-L-proline compounds are more effective than the corresponding hydroxy-D-compounds; substitution either on the oxygen or the nitrogen of the hydroxy-L-proline molecule reduces the inhibitory effect, and especially so when the substitution is on the nitrogen atom.

By the use of biosynthetic ^{14}C-hydroxyproline it was shown, unequivocally, that this acid freely entered the growing cells and was detectable as such in the alcohol-soluble extract. Any minute amount of radioactivity (3 per cent) which slowly entered the protein from ^{14}C-hydroxyproline is presumed to do so by prior conversion to proline, entry into the protein as such, and then reconversion to hydroxyproline in the protein, since both appeared in the protein in a ratio consistent with that observed when ^{14}C-proline is supplied[4].

Proline and Hydroxyproline in the Induction of Growth by Coconut Milk

Two types of response in the plant tissue cultures need to be distinguished. The first concerns the transition of the resting tissue of the carrot root into the rapidly growing state, and the second concerns the continuance of that growth once it is well established.

The first of these, namely, the growth induction phenomenon, is known to be brought about by the stimulus of the coconut milk or other fluids, and it requires a finite time to take effect; during this time, cells first enlarge more than they divide, and a phase of rapid cell division follows[7].

Other work in this laboratory has shown that during this initial induction phase the response of the tissue is sensitive to carbon monoxide and to cyanide and to relatively low dosages of radiation. Eventually, after growth has been induced, the tissue becomes less sensitive to all these adverse stimuli.

The centres at which the growth factors act to induce growth must therefore be accessible to all these antagonistic effects, and it is now seen that exogenous hydroxyproline must be included among the effects that are inimical to the cell-division growth factors provided by the coconut milk. Because the adverse effect of hydroxyproline is prevented by proline, which also enters the protein, this implies that direct incorporation of endogenous proline and its conversion to hydroxyproline in the protein synthesized is a very real part of this growth-induction response. However, after the growth induction has taken place and the tissue is well embarked upon its proliferative growth, finite amounts of proline may be incorporated with but little effect of added hydroxyproline—at least during short periods of exposure to ^{14}C-proline. Thus, again it is necessary to distinguish effects which induce growth at the outset from those that are compatible with its continuation.

Significance of the Non-labile Protein Moiety

These results parallel events that are now attracting attention in the animal body. The stimulus to collagen synthesis that often accompanies wound healing has been noted, and collagen synthesis is a feature also of some diseases, for example, arthritis[8].

It is tempting to see some structural role in the dividing plant cells for this non-labile protein, which resembles collagen in its composition but not in its solubility. The presence of pronounced cytoplasmic strands and active streaming in the free cells which grow on coconut milk media (Fig. 1) offers a suggestive location for such an elastic protein moiety. Labelling experiments are contemplated in an attempt to localize this protein in these cells, which contain this unusual plant protein in quite large amounts.

Protein Turn-over: Labile and Inert Protein Moieties

A suggestive feature of the coconut milk stimulus to the growth of plant cells is a markedly increased rate of metabolic turn-over, which involves a part only of the protein[2]; this is linked also with a similar stimulus to respiration, as shown by the evolution of carbon-14 dioxide. The carbon of the respired carbon dioxide which is linked to protein turn-over moved perforce through the sequence of protein synthesis and breakdown. But the protein of these cells also includes a part which is remarkably stable and free from such turn-over, and this part includes the combined hydroxyproline. The latter part of the protein, in fact, resembles a virus protein in that it is, metabolically, at a 'point of no return'.

Since the work on plants links the inception of this special kind of protein metabolism to the induction of growth in cells which proliferate, when attached to an explant, the interest of these phenomena in relation to tumorous growth seems clear. However, the additional fact that similar cells growing free may, in the presence of the natural nutrients for an immature embryo, develop into proembryo-like structures from which entire plantlets can be grown, sets this type of protein metabolism in a milieu from which fascinating morphogenetic events emerge.

From mature carrot phloem, to growing tissue cultures, to disassociated cells, to centres of growth out of which roots emerge, then shoots, is a remarkable morphogenetic sequence, and the significant feature is that the nutritional and special stimuli are furnished by the nutrient fluids that normally nourish immature embryos. One distinctive biochemical feature of this system, at the outset of its response, is the inception in the carrot cells of a characteristic type of protein metabolism leading to the formation of a protein which contains hydroxyproline formed *in situ* in the protein from proline.

This work forms part of a programme of research which has been supported by grants from the National Cancer Institute, National Institutes of Health, United States Department of Health, Education and Welfare, Bethesda, Maryland. Assistance with the work on aseptic culture of plant tissues was made possible by these grants and was given successively by Miss K. Mears and Mrs. M. Mapes; this is gratefully acknowledged.

GEOLOGY AND OIL

THE British Association for the Advancement of Science, Section C (Geology), held a symposium on "Geology and Oil" at the Royal College of Science and Technology in Glasgow on August 28. Sir Alexander Fleck, president of the British Association, presided over a luncheon given by the combined oil companies and representative local industries. Prof. L. R. Wager, president of Section C, took the chair for the session.

Mr. F. E. Wellings, chief geologist of the Iraq Petroleum Company, summarized the contribution of geology to the oil industry. Col. Drake's first well in 1859 was located on oil seeps. Although geologists connected the early Appalachian oilfields with anticlines, geological advice was at first resented by oil men ('wildcatters'). However, by the first decade of this century, oil companies were employing survey and academic geologists, and the United States Geological Survey began publication of studies of the geology of oil and gas. By the First World War, oil companies had permanent geological departments.

Surface mapping for anticlines, examination of drill cuttings and prediction of subsurface structure were the first geological techniques to be used. Oil is common in sedimentary rocks, but commercial oil occurs in underground traps where porous rocks, such as sandstone or limestone, are confined by impermeable rocks. Oil flows by artesian pressure of brine below it or by the expansion of natural gas in the reservoir. All the major oilfields of the Middle East are anticlines, found by geological mapping or geophysics. Systematic use of Foraminifera, microfacies and detrital minerals dates from the early 1920's. Aerial photography for mapping and photogeology, gravity survey by torsion balance and subsurface mapping by refraction seismic work began about the same time. Gravity and seismic methods discovered their first oilfields in 1924. Schlumberger electrical well logging of boreholes began in 1928. The replacement of the torsion balance by the gravimeter, refraction by reflexion seismography, improved coring and logging techniques and innovations such as ecology and gamma-ray logging make oil geology a dynamic science. Improved interpretation and presentation of results is important and a new hybrid personality, call him a 'geophysical geologist' or 'geological geophysicist', is best qualified for future oil finding. Repressuring by gas or water injection, to give secondary recovery of oil, demands more geological knowledge and engineering skill, but costs rise while the value of the oil does not. Geological survey is cheap, seismic prospecting is 10–15 times as expensive, whereas drilling costs twice that. Increased geological efficiency leading to drilling fewer dry holes therefore offers big savings. There is as yet no direct physical way of detecting actual accumulations of oil. "Oil is where you find it" and the only final test is the drill. Great technical effort will be required from geologists to meet the expected doubling of demand for oil in the next twenty years. There must, too, be the urge. Because the rewards of success are so great, the oil geologist must temper scientific caution with optimism.

Dr. A. H. Smout of the Iraq Petroleum Company explained the theory and practice of microfacies work. The method was described by H. B. Milner in 1926, but the term was introduced by Prof. J. Cuvillier in 1951 in presenting his beautiful photographs of thin sections of limestones from Aquitaine. It implies the sum of the lithological, mineralogical, textural and fossil characters of a sedimentary rock as seen in thin section. Although there is a background of detailed investigations by any means deemed suitable, routine microfacies work relies on simple inspection, usually at a magnification about × 25, and without petrological microscope equipment. Most common sedimentary minerals and many microfossils, particularly Foraminifera, can be identified and various details otherwise invisible give information. Simple comparison of appearance is often sufficient for local correlation or broad stratigraphical use. Textures, however, reveal index species and facies indications. The original sedimentary grains reveal their origin and much about their transport and deposition. For example, a freshwater limestone differs from a marine one, and depth zonation of paleogeographical facies is often found. Wind-blown sand grains differ obviously from water-worn ones. Secondary textures arise in diagenesis, partly or wholly altering the original texture, such as the recrystallization of aragonite to calcite. Metasomatism, altering calcite to dolomite, iron ore, flint, etc., involves bulk replacements of elements in the solid rock, but often the original characters can still be stated. Low-grade metamorphism may be seen. Strain texture in the form of calcite veins, stylolitic sutures or cleavage of minerals may be found.

The industrial value of microfacies work depends on its rapid routine empirical use; a determination being possible within one hour of sampling if necessary. It offers direct comparison between outcrop samples, cores and well cuttings, often as small as a pea. Its value is greatly increased by the additional information on facies variation. The amateur geologist will find the method possible with the minimum of equipment, but like the expert must persevere until he knows the appearances of all the local hard rocks. Limestones are easy to section and give the greatest variety of geologically significant variations.

The close relationship of geology and geophysics in oil exploration was emphasized again by Mr. D. R. Brown, chief geophysicist of Iraq Petroleum Company. Physical measurements permit an extrapolation of the geological observations at the surface or in wells, but lead to a final interpretation in geological terms which can only be developed by close collaboration.

Since the War the Iraq Petroleum Company group of companies have observed nearly 250,000 stations in gravity reconnaissance and covered about 15,000 miles of more precise seismic traverse. Normal development from a tenuous gravity lead and a semi-detailed seismic survey was illustrated by the results discovering the prolific oil-fields of Zubair and Rumaila in the Basrah area of Iraq. Additional knowledge of the distribution of seismic velocities in this area is still being built up and is aiding the final appraisal of the sub-surface structures needed for their efficient development.

Improved techniques and instrumentation are now being applied to the detailed seismic work. Areas of loose sands or cavernous limestones, previously unworkable, now yield readable reflexions to multiple patterns of shot-holes and geophones which direct and concentrate the ground energy. Magnetic tape recording allows the analysis of the received energy and accentuation of the particular characteristics desired. The recognition and elimination of disturbing reverberations give a truer knowledge of the velocity distribution in depth.

Electronic or photographic reproduction of a series of records with appropriate corrections simplifies the calculations and interpretation from the resultant cross-sections.

The logistics of maintaining the large amount of equipment present major problems in the more remote desert areas, particularly if continuous working throughout the summer months is desired. Recently, a survey in the marsh areas north of Basrah has required the development of a special floating camp and working equipment of a type not usually associated with Middle East regions.

Dr. J. Birks of the British Petroleum Company briefly described the logs which are commonly used in the course of drilling oil wells. These are drilling, geological, drilling mud, geochemical and core analysis logs, but the term 'well logging' is now generally applied to electrical and radioactive measurements of the rocks and their fluid contents.

Electrical and radioactive well logging are comparatively recent innovations, but they have become essential exploration tools. Four main groups of instruments are now used. Electrical sondes measure the depth, diameter and inclination of the borehole; electro-mechanical sondes measure temperatures and pressures and give the flow-rate of fluids produced from or injected into the hole; electrical sondes measure the resistance of the rocks, their water, oil or gas contents, the salinity of the water and, in modified form, give the angle and direction of dip of the strata; radioactive sondes measure the natural gamma-radioactivity of the rocks and the induced radioactivity (the neutron log).

A complete section of the borehole can be logged and the results presented on a small number of charts. A complete pattern of the borehole is available to the geologist, who can compare the lithology of the drill cuttings with the log data and define the sand/shale sequences, coal seams, limestones, etc. Detailed interpretation gives porosities, water content and salinity, and zones of oil and gas accumulation. The only important rock property not yet measurable by logging is permeability, that is, its ability to produce fluid into the borehole. This must be measured by production test, but the zones to be so tested are decided from the electrical and radioactive logs.

Recent developments are the presentation of logs in variable density form and the use of television cameras in boreholes.

Mr. N. L. Falcon, chief geologist of the British Petroleum Company, concluded the symposium with an address on the contribution of oil exploration to the advancement of geological science. The word geology was used in the widest sense to include all knowledge having a bearing on the constitution of the Earth's crust. Previous speakers had dealt with the assistance which geology and allied sciences gave to oil exploration and the final talk had as its theme the manner in which oil exploration repays the debt. Oil exploration has added an enormous amount of world-wide factual data to the general fund of geological knowledge. Geological research begins with reconnaissance but rapidly tends towards the study of available evidence in greater and greater detail. The great contribution the international oil industry makes to geology is to extend the reconnaissance phase of research into inaccessible places all over the world, below the surface as well as on it.

Large areas of the Earth would not yet have been mapped had it not been for oil exploration. The information from boreholes represents the examination of 50,000 miles of continuous vertical section each year, for in the United States alone 45,000 miles of hole are drilled yearly. The wealth of information so obtained has led to development of isopachyte and facies maps and the study of deltaic deposits. It has also resulted in a greatly increased knowledge of rock deformation before elevation and erosion.

Other important contributions to geological science by oil exploration were discussed, for example, in the field of micropalaeontology particularly with reference to Foraminifera, in photogeology where present techniques have to a great extent been developed within the oil industry, in electrical logging devices and in the development of geophysical tools for sub-surface exploration.

Mr. Falcon concluded by stating that the term 'oil geology' tends to obscure the fact that here is one branch of geology which is devoted to accumulating knowledge about the Earth's crust and that the geologists serving the industry have exceptional opportunities for doing so. Much information has been released; much more could not be released for various reasons not the least of which is the effort required to collate and publish the wealth of factual data available. That already published presented an embarrassing bulk.

An exhibition of oil geology and geophysics was open for the whole week of the British Association meeting. This was arranged on behalf of the British Association by the British Petroleum Company, Ltd., with assistance and contributions from Burmah Oil Company, Ltd., Iraq Petroleum Company, Ltd., Kuwait Oil Company, Ltd., and Shell Petroleum Company, Ltd. Actual samples, instruments and primary records, photographs of geological operations and final interpretations of geological results in the form of geological and geophysical maps, and of models of subsurface geological structure, were on display. The exhibition aroused considerable interest, particularly among the many members who had connexions with other industrial applications of geology. Mr. V. W. Baker, of the British Petroleum Company, Ltd., displayed the exhibition to the maximum advantage in the ideal surroundings of the laboratories of the Department of Mining of the Royal College of Science and Technology generously made available by Prof. G. Hibberd.

A. H. SMOUT

DEPOSITION OF STRONTIUM-90 AND ITS CONTENT IN VEGETATION AND IN HUMAN DIET IN THE UNITED KINGDOM

By DR. R. SCOTT RUSSELL

Agricultural Research Council Radiobiological Laboratory, Grove, Wantage, Berks

Introduction

If strontium-90 is deposited either at a relatively steady rate as in world-wide fall-out or in a sudden deposition of short duration, as might occur after a reactor accident, its long-term consequences can be assessed only if the mechanisms whereby it enters plants, and hence reaches human food, are understood. On the simplest analysis the strontium-90 in plants can be divided into two components, namely, that which lodges on the leaves, stems or surface roots and is absorbed by them, and that which is absorbed after incorporation into the soil. If the deposition is continuous, the former component will depend on the quantity deposited during the life of the plant, and it is therefore a function of the rate of fall-out; the latter component will depend on the cumulative deposition. It is thus necessary to solve the equation:

$$C = aD_p + bD_T \qquad (1)$$

when C is the strontium-90 content of the plant; D_p and D_T are the deposition during the life of the plant and the cumulative deposition respectively, and a and b are proportionality functions. For any one species in a given environment a should be relatively constant with time; as will be shown later, however, b may change progressively.

If strontium-90 is released for a short period only, equation 1 should be applicable to plants growing at that time. Afterwards, however, the relevant equation will be:

$$C = bD_T \qquad (2)$$

The same equations can be applied to agricultural products, such as milk, which contain strontium-90 derived from vegetation.

An attempt is made here to solve these equations in the light of the results both of surveys of world-wide fall-out[1,2] and field experiments in which radioactive strontium has been applied to the surface of land which has been afterwards cultivated as nearly as possible by normal agricultural methods[3,4]. The present conclusions are tentative only; they appear, however, to provide the best fit to the data at present available.

General Aspects of the Behaviour of Strontium-90 in Plants and Soils

The movement of strontium-90 through food chains is similar to that of calcium but not identical with it, and the hazard to the human population from the ingestion of strontium-90 depends largely on the quantity of calcium with which it is accompanied, as the two ions are laid down side by side in bone. Thus the comparison of their behaviour is of particular importance. Strontium, like calcium, is relatively immobile once it has reached the leaves of plants, and for practical purposes its subsequent transfer to other tissues can be ignored. Some discrimination between the two ions occurs within plants, and the ratio of strontium to calcium in roots normally exceeds that in shoots. The overall effect of this discrimination is, however, small, and water-culture studies indicate that in a practical assessment the ratio of strontium-90 to calcium in plant shoots can be regarded as similar to that in the outer medium; no large intraspecific differences in discrimination between strontium and calcium have been established[5].

Water culture studies show that the rate of absorption of strontium is closely dependent on the external concentration of strontium plus calcium[6,7]. This simple relationship has, however, not been borne out in a number of investigations in which plants have been grown in soil[8,9]. This appears to be because conventional methods for soil extraction are inadequate to assess the availability to plants of strontium-90 relative to soil calcium; there is evidence that strontium-90 and calcium are absorbed in proportion to their concentrations in the equilibrium soil solution, and methods for measuring this ratio are under investigation[10]. In subsequent discussion the term 'ratio of strontium-90 to calcium' in soil is used with respect only to the fractions of the two ions which are of comparable availability to plants.

The study of the absorption of strontium-90 from world-wide fall-out under field conditions is complicated by its non-uniform distribution in the soil profile. More than 70 per cent of the strontium-90 as yet deposited by world-wide fall-out is in the upper 5 cm. of undisturbed soil[11]; numerous laboratory experiments have confirmed its slow downward movement[12]. Thus the ratio of strontium-90 to calcium varies greatly through the soil horizons from which plants absorb ions. With the passage of time, especially if ground is cultivated, the distribution of strontium-90 will become more uniform, so that even if no further strontium-90 enters, the ratio of strontium-90 to calcium in the rooting zone may change. For example, if plants absorb the major part of their nutrients from the upper soil layers the ratio of strontium-90 to calcium accessible to them should decrease steadily with time. The extent of this effect is indicated by field experiments in which rye-grass was grown in soil to which a constant quantity of strontium-89 was applied either as a surface dressing immediately after the sowing of the seeds or alternatively was cultivated into the soil to different depths[4]. Ploughing to 12 in. (Table 1) caused the ratio of strontium-89 to calcium in plants to be on the average only 30 per cent of that resulting from a surface application. More deeply rooted crops, for example cereals, were less affected by the depth of placement of strontium-89. There is no evidence that strontium is fixed in soils in a manner comparable with that which occurs with potassium or phosphate[12], but it is clear from Table 1 that the progressive mixing of strontium-90 in the soil, which will occur especially rapidly if land is cultivated, may result in its accessibility to plants decreasing steadily relative to that of calcium. Thus over long periods the function b in equation 1 cannot be regarded as a constant.

Extent of Absorption of Strontium-90 from Soils by Plants under Field Conditions

As world-wide fall-out continues, the quantity of strontium-90 in the soil will become progressively greater relative to that which is deposited annually. Thus the absorption of strontium-90 from the soil should contribute an increasing fraction of the total plant content. The prediction of long-term trends is therefore possible only if the extent of absorption of strontium-90 from soil is known. Attempts have been made to study this question by applying equations similar to equation 1 to the results of surveys of world-wide fall-out[13]. This approach is considered unsatisfactory since it implies that the function b in equation 1 is a constant. Furthermore, the method is unavoidably imprecise when the component of plant content which is dependent on the rate of fall-out (aD_p) is relatively large, since the soil component (bD_T) is then a small difference between two large quantities. The results of field experiments therefore appear to provide a more satisfactory basis for assessment.

Notes: Columns 1 and 4—values were determined by extraction of soil with *N* ammonium acetate and are expressed as milli-equivalents Ca/100 gm. soil. Column 2—shows results of a survey of cultivated agricultural soils (ref. 14). Column 6—calculated by multiplying column 5 by column 2. By summing the entries for the four soil calcium classes the country-wide mean, weighted for the areas of different soil types, is obtained.

For this purpose the results of six experiments on contrasting soil types have been used[4]. In each, three test crops were grown (a grass/clover mixture, cereals and either a 'root' or a forage crop) after strontium-89 had been incorporated into the soil by the three cultivation procedures indicated in Table 1. The results were corrected for radioactive decay so that the fate of strontium-90 can be inferred. In Table 2 (cols. 3–5) the mean result for all cultivation treatments and all crops in each experiment are expressed as ratios of strontium-89 to calcium, and not as percentages of strontium-89 absorbed, since the latter will vary more with crop yield. The ratios of strontium-89 to calcium in plants were highest in soils of low calcium content. However, the observed differences should not be taken as a basis for generalization with regard to the effect of soil calcium, since it appears[4] that factors other than soil calcium were important in determining the strontium-89 content of plants grown in the soil of lowest calcium content. None the less, variations in soil calcium must be taken into account in the construction of a country-wide mean. To this end the results of the experiments have been weighted in accordance with the fraction of the total cultivated land in England and Wales which is of similar calcium status[14]. Hill grazing has been excluded as it is a minor source of dietary calcium. On this basis the country-wide mean value is 1·1 $\mu\mu$c. strontium-90/gm. calcium in plants when the deposition is 1,000 $\mu\mu$c. strontium-90 per m.^{2} (that is, 1 mc./km.^{2}).

Although this calculation appears to be less questionable than the use of the result of surveys of world-wide fall-out, the present figures must be treated with caution. The experiments span the range of calcium content in British soils but they cannot be regarded as truly representative; no account has been taken of factors other than soil calcium which affect the absorption of radioactive

strontium. Moreover, the experiments have been carried out for only one season and since the strontium-90 has not been incorporated as fully in the soil profile as would be the case under continuous cultivation (on the average of all treatments 50 per cent remained in the top 4 in.) it is probable that the situation which would occur after long periods of cultivation has been overestimated.

World-wide Fall-out: the Present Mechanism of Entry of Strontium-90 into Vegetation

Estimates of cumulative deposition of strontium-90 in the United Kingdom have been made[15] and ratios of strontium-90 to calcium in vegetation and milk have been reported[1,2]. A comparison has been attempted (Table 3) between the observed values in vegetation and in milk with those which would have been expected from the data in Table 2 if contamination had been due to absorption from the soil. This comparison is not precise as no results are at present available for samples representative of the country's agricultural production as a whole. With regard to milk it has been assumed that there is a discrimination factor of 0·14 against strontium relative to calcium in its passage to milk[5], and that 20 per cent of the calcium in the diet of cattle is relatively uncontaminated (more than 30 per cent of dietary calcium is likely to come from sources which are only slightly contaminated relative to grass, for example, roots and 'concentrates'). In only a few cases, noted in Table 3, has it been possible to make allowance for variations in the deposition of strontium-90 from one part of the country to the other or for the level of soil calcium. The results of surveys of permanent pastures in hill areas[1] have been excluded for reasons which are discussed below. A further source of error in the present comparison is that the lack of quantitative data has made it necessary to assume that the ratio of strontium-90 to calcium in the edible tissues of vegetables is similar to that in the whole plant.

Table 3 shows that for milk and permanent pastures the observed values exceed those expected if absorption occurred from the soil by factors of 8–15. This suggests that more than 80 per cent of the strontium-90 in these materials has not passed through the soil. For the annual vegetable crops the values approach more closely to 1; thus it appears that the major fraction of the strontium-90 in these crops was absorbed from the soil excepting possibly only lettuce, the one vegetable examined of which the exposed leaves are edible (the interpretation of the results for potatoes is difficult since they were not peeled prior to assay).

An examination of results for hill pastures strengthens the inference that the contamination of permanent grass cannot be attributed to absorption from the soil. Ratios of strontium-90 to calcium ranging up to 2,100 $\mu\mu$c. strontium-90/gm. calcium are reported, that is to say, nearly 50 times the mean for lowland pastures[1]. As soils comparable to those of these hill areas were not employed in the field experiments, the quantity of strontium-90 which would have been expected to be absorbed from soil cannot be estimated by the method adopted in Table 3. Some basis for assessing the extent of absorption from the soil is, however, possible from the results of preliminary laboratory experiments, in which rye-grass was grown in soil from these areas which had been contaminated with strontium-89. A comparison of the results of the tracer experiments and field surveys suggests that the ratios of strontium-90 to calcium in native vegetation of different types are 4–40 times greater than would have resulted from absorption from the soil[16].

Since milk is at present the major route whereby strontium-90 reaches human diet it is particularly important to interpret the mechanism whereby strontium-90 enters the herbage of permanent pastures which cattle graze. As the contribution of strontium-90 from the soil appears to be relatively small, the major route of entry must be through leaves, stems or surface roots. Direct foliar absorption is the mechanism other than absorption from the soil which has been considered in the majority of discussions hitherto. Entry by this route would be expected to depend on the rate of deposition during the growing period of leaves, that is to say, it should be a function of the annual rate of fall-out. Data for lowland pastures and for milk in the United Kingdom are reasonably compatible with this interpretation. In the period 1955–56 when the rate of annual fall-out was relatively constant and the cumulative total

increased by a factor exceeding two, levels in milk rose to a comparatively small extent (Table 4).

Direct foliar absorption cannot, however, explain the situation in hill pastures since the ratios of strontium-90 to calcium in them increased between 1955 and 1957 in a manner comparable to the cumulative fall-out[1]. This has led to the suggestion that the high ratio of strontium-90 to calcium in such pastures is due to rapid absorption from soils low in calcium. Evidence already considered suggests that this is improbable; a more cogent reason for rejecting this interpretation is that a major part of the strontium-90 in these areas is in the root mat, not in soil. The permanent unimproved hill pastures of the United Kingdom are characterized by a considerable development of root-mat which consists of organic matter, superficial roots, and the basal portions of stems in varying proportions. Between different habitats the depth and nature of the mat zone varies greatly; in some cases it is many centimetres in thickness. All such mat layers have one characteristic in common: strontium-90 entrapped therein will not have equilibrated with the labile soil calcium. It may therefore be expected to be more accessible to plants than strontium-90 in the soil. To distinguish absorption by this route from direct foliar uptake, and from absorption from the soil, the term 'stem-base' absorption is proposed; it may be regarded as an intermediate condition between the other two mechanisms of entry. Grassland husbandry provides evidence of the magnitude of the 'stem-base' absorption; fertilizers frequently have greater effect when applied superficially to establish grass than when added to soil. Since the stem-base 'reservoir' will not retain strontium-90 indefinitely, entry by this route will be dependent on the rate of fall-out rather than the cumulative total. With annual species it will be expected to be a function of the deposition during the growing seasons but with perennial pastures it will be a function of the deposition during the mean period for which strontium-90 remains in the stem-base reservoir. Thus the apparent relationship between the content of strontium-90 in hill vegetation in the United Kingdom and the cumulative deposition during the period 1954–56 is suggestive that the mean life of strontium-90 in the stem-base reservoir in these areas is several years; the fact that in 1957 soil has been found to contain less than 40 per cent of the total strontium-90 per unit area of pasture in some hill areas supports this interpretation.

Stem-base absorption is therefore considered to provide an explanation of the observed high levels of strontium-90 in hill pastures. This prompts inquiry as to whether the large component of the strontium-90 in lowland pastures which is dependent on the annual rate of fall-out is correctly attributed to foliar absorption or whether it is due to stem-base absorption from a reservoir which in this case retains strontium-90 for a mean period of approximately one year. Several lines of evidence suggest that this may be so. In one of the field experiments already referred to[4] an additional treatment was included in which strontium-89 was applied to established grass in its second year and the ratio of strontium-89 to calcium in the new leaf tissue which developed 5–28 weeks after contamination was nearly twice that in treatments in which strontium-89 had been applied to the surface of the land prior to the germination of grass; stem-base absorption would be expected to be much smaller in such a young sward than in established pastures with the greater mat development.

The possibility that stem-base absorption may be large relative to direct foliar uptake is also encouraged by the fact that when strontium-89 is applied as a spray to leaves, and allowed to dry, considerable losses can rapidly occur through leaching in rain[17]. Thus the quantity of strontium-90 which reaches the stem-base reservoir may well be very much greater than the fraction which remains on leaves.

Surveys of world-wide fall-out in the United Kingdom indicate that the relationship between the ratio of strontium-90 to calcium in plants and the cumulative deposition varies by a factor in the order of 20 between hill and lowland pastures. The data[1], however, show that the relationship between the strontium-90 content of grass per unit area of land and the total deposition is considerably more constant; there is no indication of a significant difference between hill and lowland areas. This encourages the view that the mechanism whereby strontium-90 enters pasture plants may be relatively similar in all cases; the only mechanism which appears compatible with results obtained in both hill and lowland pastures is stem-base absorption. None the less, no unequivocal evidence is available to show the relative magnitude of foliar and stem-base absorption except in hill pastures where the latter appears to be dominant.

Future Relationship between the Rate of World-wide Fall-out and the Strontium-90 Content of Vegetation and Milk in the United Kingdom

Despite uncertainty as to the relative importance of foliar and stem-base contamination in lowland pastures and in annual vegetable crops, it appears that the component of contamination of these crops which is dependent on the rate of fall-out (that is, aD_p in equation 1) is a function of the annual deposition. No precise estimate of the proportionality function a in equation 1 is at present possible, but an approximation can be made by dividing the difference between the values in columns 4 and 5 of Table 3 by the annual rate of fall-out. The resultant estimates of a for milk, lowland pastures and vegetables are shown in Table 5. Values for the proportionality function, which is dependent on the cumulative deposition (b in equation 1), can be derived directly from Table 2 for lowland pastures and for annual vegetables; the appropriate value for milk can be obtained by dividing the value for lowland pastures by 0·14, which is taken as the discrimination factor between strontium and calcium in their passage from the diet of cattle to milk[5]; no allowance for uncontaminated sources of calcium in the diet of cattle is here made, as was done in Table 3, since it is to be

Table 5. Proportionality Factors for the Estimation of Levels of Strontium-90 in Biological Material by Equation 1

Factor	Milk	Lowland pastures	Annual vegetables
a, Dependent on rate of deposition ($\mu\mu$c. Sr-90/gm. Ca per mc./km.^{2} deposited per annum)	1·8	18	2·8
b, Dependent on cumulative deposition ($\mu\mu$c. Sr-90/gm. Ca per mc./km.^{2} total deposition)	0·16	1·1	1·1

expected that in due course all the dietary calcium of cattle will be contaminated to a similar extent.

In Table 6 the values of *a* and *b* shown in Table 5 have been used for calculating the levels of contamination in milk lowland pastures and edible vegetables which may result if world-wide fall-out continues at its present rate. Stewart *et al.*[15] have concluded that a constant rate of fall-out will result in the cumulative deposition in the United Kingdom rising from the 1957 level of 7·5 mc./km.^{2} to 38 mc./km.^{2} in 1967; an equilibrium value of approximately 92 mc./km.^{2} would be attained in a hundred years time. Predicted levels of strontium-90 in milk and vegetation for these two occasions are shown in the table. It is estimated that at equilibrium, when cumulative fall-out has attained twelve times the present level, the contamination of milk and lowland pastures in the United Kingdom will have risen only three to four times; the corresponding value for annual vegetables, the contamination of which is more dependent on absorption from the soil, is seven.

In view of the attention which has been directed to the present relatively high levels of strontium-90 in hill pastures, it is of interest to consider the eventual levels which may be attained in them. The method of Table 6 cannot be used since the rate-dependent component (aT_p in equation 1) cannot at present be assessed. The evidence, however, suggests that this component (that is, stem-base absorption) is greater relative to absorption from soil than in lowland pastures. Thus it is to be anticipated that the eventual values for hill pastures will exceed present levels by smaller factors. In any event, the situation in permanent hill pastures is of relatively small importance in determining the exposure of the population since they provide but a small fraction of dietary calcium.

The very slender basis for the present predictions must be emphasized; it may well be that in the early period the levels in permanent pastures will rise more rapidly than predicted because strontium-90 remains largely in the upper soil layers (Table 1). On the other hand, the eventual level is likely to be reduced both because no allowance has been made for the strontium-90 removed in crops and animal produce each year and because leaching and the removal of strontium-90 in surface-wash from sloping land may cause the cumulative level in the soil to fall significantly below the total cumulative deposition. Such losses of strontium-90 should in general be expected to be greatest in leached soils which are low in calcium; thus with the passage of time the effect of soil calcium indicated in Table 3 may be reduced. The regular application of lime would also reduce the effect of soil calcium. A further reason why the present calculations may over-estimate the eventual level of strontium-90 in plants is that, in the field experiments, the radioactive tracer was not as uniformly distributed in the soil as would occur after continued cultivation.

Release of Strontium-90 in Accidents: Relationship between Deposition and the Contents of Plants and Milk

The circumstances of an accidental release are likely to differ from world-wide fall-out in two respects. First, the deposition may be of relatively short duration; secondly, whereas world-wide fall-out is carried down largely in rain[15] the deposition resulting from accidents may consist of particles of considerable size. Since particles exceeding 40μ are relatively little retained in vegetation[18], foliar uptake may vary greatly; furthermore, the biological availability of the deposition may show similar variability. It is, therefore, impracticable to predict the magnitude of the proportionality factors *a* and *b* for equation 1. The maximum level in vegetation which grows in land cultivated after the deposition should, however, be given by equation 2; low biological availability may on occasions introduce a large protective factor.

Comparison of the Rates of Entry of Strontium-90 into Plants under Different Climatic and Agricultural Conditions

From the foregoing it is apparent that the nature of vegetation can cause large differences in the relative magnitude of the components of plant contamination which are respectively dependent on the rate of deposition and on the cumulative deposition. If the component which is dependent on the rate of fall-out is large the current level of contamination would be expected to be relatively high, but with the passage of time it will not increase as rapidly as in areas where

Table 6. Prediction of Future Contamination of Milk, Lowland Pastures and Annual Vegetables with Strontium-90 assuming that Fall-out continues at its Present Rate

Material	Year	Cumulative deposition		$\mu\mu$c. Sr-90/gm. Ca in biological material			
		mc./km.^{2}	relative to 1957	Component dependent on rate of deposition (aD_p in equation 1)	Component dependent on cumulative total (bD_T in equation 1)	Total	Ratio: $\frac{\text{total}}{\text{1957 value}}$

	2057 (equilibrium)	92	12	7	101	108	7

Columns 3 and 4 from Stewart *et al.* (ref. 15); column 5 calculated by multiplying annual rate of fall-out (ref. 15) by values of (*a*) shown in Table 5; column 6 calculated by multiplying column 3 by values of factor (*b*) in Table 5.

contamination is primarily dependent on the cumulative deposition.

It is of interest to compare the relationships between the cumulative deposition and the strontium-90 content in milk for Somerset and New York in the past four years (Table 4). In the United Kingdom the levels in milk have risen to only a small extent, although the cumulative deposition has been more than doubled ; in New York, however, the cumulative deposition and the levels in milk have both risen similarly. Moreover, the ratio of the level in milk to the cumulative deposition on Somerset (Table 4, col. 3) is considerably above the relatively constant United States value ; the over-all rate of transfer of strontium-90 to milk is, therefore, considerably greater. This is perhaps attributable in part, at any rate, to the conditions of United Kingdom pastures being more favourable for stem-base absorption. These differences indicate the danger of extrapolating from one region to another. This danger is likely to be particularly great when the manner of growth of crops contrasts markedly. It might be expected that the component of plant content which is dependent on the rate of fall-out will be particularly great in plants growing in soil submerged in water, particularly if ions can be absorbed largely from the water as opposed to the soil ; this could be regarded as an extreme case of stem-base absorption. A report that the total radioactivity of the bog moss *Sphagnum* in the United Kingdom has increased to a considerably greater extent than that of land plants[19] is compatible with this view. Rice grown in flooded paddy fields would seem to provide the opportunity for an analogous large component dependent on the rate of contamination. Relatively high levels of contamination in rice have been reported, but the evidence does not enable the mechanism of contamination to be assessed.

Hitherto it has usually been considered that variations in the rate of transfer of strontium-90 from the ground surface into human diet will be influenced mainly by the importance of milk produce in the diet and by the calcium content of soil. It now appears that this analysis is inadequate ; variations in the growth forms of both roots and shoots may cause considerable differences in the relationship between plant content and both the rate of fall-out and the cumulative total. The results of field surveys, conducted for at most a few years, appear wholly inadequate for elucidating these complex relationships. If long-term predictions are to deserve credence, careful experimental work is necessary.

OBITUARIES

Prof. S. R. Milner, F.R.S.

PROF. SAMUEL ROSLINGTON MILNER died at the home of his son in Sydney, New South Wales, on August 12, at the age of eighty-three. For some time his health had not been good, but he continued working to the end. An understanding friend has written of him : "In the entirely selfless absorption in science for truth's sake there cannot have been at any time many equals of S. R. Milner".

He attended King Edward VI School, Retford, and the Universities of Bristol and Göttingen, under Chattock and Nernst. After one year on Schuster's staff in Manchester he worked in Sheffield as a lecturer with Hicks from 1900 until 1917, as acting professor until 1921 and as professor until his retirement in 1940. During the First World War he enlisted in the R.A.M.C. as radiographer to the Third Northern General Hospital, designing and building the necessary apparatus and training men for other hospitals.

In spite of a heavy burden of teaching in an understaffed Department, Milner fulfilled his early promise by a fruitful output of both theoretical and experimental research. At the early age of twenty-five he was awarded the London D.Sc. and later received honorary doctorates from both Bristol and Sheffield. A beautiful and ingenious experimenter, it was a delight to watch his careful construction and manipulation of apparatus. Students will always remember his lectures, which were models of lucidity and copiously illustrated by demonstrations, many of his own devising.

His colleagues and others had a tremendous admiration for his encyclopædic knowledge of physics ; but it was his theoretical work on solutions, and later on electromagnetism, which brought him his greatest distinction. Considering first the effect of the departure from the ideal gas laws of the ions in solutions (1900), he developed his ideas in further papers and laid the foundations of the modern theory of electrolytes (1912–1918) in papers on "The Virial of a Mixture of Ions" and "The Effect of Interionic Forces in Electrolytes". For this work he was elected to fellowship of the Royal Society in 1922. Though these papers were necessarily mathematical, he kept the physical basis in the foreground, and this was true also of his later approach to electromagnetic theory. He examined first the motion of, and stresses in, tubes of force and built up an analysis of the field into moving elements before his thought matured into more mathematical expression of the 'action' of an electromagnetic field, on which his later work was based. He found tools for the development of his ideas in Eddington's 'E-number' calculus, which he reduced to order, obtaining thereby a new insight into the roots of relativity. Thus he was enabled to formulate for the first time a self-consistent classical theory of electromagnetism. At the time of his death he was engaged in the preparation for publication of further papers in which this theory is expounded.

Milner was the most lovable of men. His outstanding characteristic was his capacity for inspiring affection. He was the friend of all because he was so willing to be friendly and helpful in a rather shy and retiring way. His genuine interest in the welfare and careers of his students was recognized and appreciated by them. Together with his colleagues and many others, they had for him a very deep affection. He is survived by his wife, also a physicist from the University of Bristol, and son, who is professor of physics in the New South Wales University of Technology, Sydney.

J. R. CLARKE

Mr. S. E. Fox

MR. SEATON E. FOX, who was sixty-five, died in a London hospital on August 27 after a short illness. He was a graduate of the University of Cambridge and in 1932, after working for several years in the explosive and petroleum industries, he became assistant secretary and technical editor to the Technical Section of the Paper Makers' Association, and in 1944 he was appointed librarian, information officer and editor to the British Leather Manufacturers' Research Association, a post he occupied until his death.

During his fifteen years work for the Association, Mr. Fox organized its publications on a sound basis and brought them to a high technical and editorial standard. He began the abstracting system which has proved so useful to members of the British Leather Manufacturers' Research Association: his index of publications on collagen is valued not only by his colleagues and others in the leather industry but also by scientists engaged elsewhere in pure research on that subject. His work was highly respected by librarians and editors in other research associations, and his death is greatly regretted by them and by his many friends and acquaintances in the leather industry.

NEWS and VIEWS

The Danish Atomic Energy Commission

THE main task of the Danish Atomic Energy Commission, which was constituted on December 21, 1955, and which meets regularly once a month under the chairmanship of Prof. Niels Bohr, is the planning and construction of Risö, its research establishment, situated on a 650-acre site four miles north of Roskilde, a town of 30,000 inhabitants, and twenty miles west of Copenhagen. Through the co-operation of the United States of America and the United Kingdom the establishment will eventually have the facilities of three research reactors. DR1 (Danish reactor No. 1) is a low-energy, homogeneous reactor, particularly suitable for educational purposes and physical experiments. It was purchased in the United States in July 1956, together with DR2, which is a light-water-moderated heterogeneous tank-type research reactor with facilities for neutron exposure experiments and isotope production. DR3, purchased in the United Kingdom in June 1957, is a heavy-water-moderated high-flux reactor of the PLUTO-type as constructed for Harwell and Dounreay. Work on DR1 was completed on August 15, 1957, and DR2 and DR3 are expected to become operational during 1958 and 1959, respectively. Details of the layout of the establishment and of the components of the reactors, together with illustrations of the various ancillary buildings, are given in an attractive brochure which has recently been issued by the Commission (Risö: The Research Establishment of the Danish Atomic Energy Commission. Pp. 20. Copenhagen K: Danish Atomic Energy Commission, 1958). The staff of the Scientific and Technical Department on April 1, 1958, totalled 143, distributed among the six groups of the Department—reactor engineering, physics, chemistry, electronics, health physics and agricultural research. In addition, fifty-one people were employed in the administrative office and the various service departments at Risö and thirty in the secretariat of the Commission at its headquarters in Copenhagen.

Seventy-fifth Anniversary of L'École Supérieure, Paris

To commemorate the seventy-fifth anniversary of the foundation of L'École Supérieure de Physique et Chimie Industrielle in Paris in 1882 the student association has recently issued a most attractive and interesting illustrated volume containing twenty-four articles dealing with chemical and physical topics (Association des Élèves de l'École Supérieure de Physique et Chimie Industrielles de la Ville de Paris. Physique et Chimie. Ouvrage édité à l'Occasion du 75e Anniversaire de leur École. Pp. 272. Paris, 1959). In the first two articles, Prof. R. Lucas, the director of L'École Supérieure, and Prof. L. de Broglie pay tribute, respectively, to the founders and to the many famous past pupils of the institution, and one of these pupils, Paul Langevin, is also the subject of a separate article by Prof. M. Tournier. The articles by the late Prof. F. Joliot on energy and its utilization, Prof. G. Destriau on the phenomena of luminescence, and Prof. J. J. Trillat on electron diffraction, will perhaps be of greatest interest to the physicist; and to the chemist, the articles describing the French chemical industry, polyamide textiles, quantum chemistry, and plastics. There are in addition articles dealing with optical methods for the study of the flow of liquids; the optics of high-frequency aerials; and the visibility of submerged objects. In the final article in the volume Prof. D. Gabor gives a detailed and clear description of his flat colour-television tube which has aroused so much interest both in Britain and overseas.

University College of the West Indies

It is widely recognized that a degree course in agriculture should be available in the West Indies, and for some time the Council of the University College of the West Indies and the Governing Body of the Imperial College of Tropical Agriculture have considered how to provide it. The Governing Body of the Imperial College of Tropical Agriculture has recently proposed that the Imperial College should merge its identity in the University College of the West Indies and become its School of Agriculture. The Council of the University College has welcomed the proposal and is discussing means of giving effect to it in the near future. The degree course would replace the present course for the diploma of the Imperial College of Tropical Agriculture, but the other activities of the Imperial College, including its post-graduate teaching and research, would be continued in Trinidad under the auspices of the University College. At the request of the two Colleges the Secretary of State for the Colonies has agreed to the secondment of Sir Stephen Luke from the Colonial Office to assist them in the preparation of a scheme.

Professional Civil Servants

In an article on "The Role of the Professional Civil Servant" reprinted from *Scientific Service in State Service* of August, Sir Graham Sutton expresses the view that in the future it will be increasingly necessary for professional Civil servants to participate in administrative functions: the management of a research group or of any part of a Ministry concerned with scientific and technical matters should be largely in the hands of men with professional knowledge. Sir Graham regards the making of decisions on the basis that he who is completely ignorant cannot be biased is a most dangerous feature of to-day and agrees, on the other hand, that the whole basis of scientific training makes it extremely difficult for the scientist or engineer to go against the weight of evidence. Accordingly, he suggests, a main problem facing professional Civil servants is how to ensure that an adequate knowledge of administration and management is passed on to the young professional man in his formative years. He believes that in any well-balanced government service of the future the fundamental position of the technically trained man must be recognized and that he should be given some training officially in administration. The professional Civil servant must endeavour to carry on the tradition of integrity, freedom from corruption and life-time devotion to duty irrespective of financial reward which had marked the Civil Service, but from the point of view that he is no longer an adviser, but likely to be the man who will actually make decisions because he alone is able to understand the scientific principles involved.

Business Schools

In an article, "The American Business School", in the *Westminster Bank Review* of May last, Mr. O. S. Hiner describes briefly these institutions and their close relations with industry and with commerce, on which their effective operation depends. First degrees in commerce and business rose from 1,559 in 1920 to a peak of 72,137 in 1950 and were more than 40,000 in 1955. The expansion has been due partly to the readiness of the universities to recognize and meet a need, though the provision made has not always been commensurate with their facilities and available teaching staff. The American Association of Collegiate Schools of Business was formed to promote and raise standards, and 90 out of about 170 undergraduate and graduate schools are members. In the belief that decisions in business require increasingly managers with a wide, balanced outlook, the business schools are offering courses intended to produce the 'general' man rather than the specialist, and they claim that their task is primarily to help provide, not departmental heads, but general managers of the future. Besides consulting work by the staff, business schools often undertake research at the request of industry, and there is also a strong demand for development programmes intended to prepare men who have attained senior positions as specialists to undertake more general managerial responsibility. Mr. Hiner suggests that these schools constitute a vital element in the range of educational possibilities and that such institutes in Britain could fill a gap in our existing educational arrangements to produce the managers we need.

Water Pollution

The Department of Scientific and Industrial Research is issuing a quarterly series of leaflets dealing with different aspects of water pollution and its control, one object of which is to direct the attention of industry to the work of the Water Pollution Research Laboratory, the scope of which is being extended with the help of a considerable financial contribution from the Federation of British Industries. The first of these leaflets (Notes on Water Pollution Research, No. 1, June 1958. Pp. 3. (Stevenage, Herts: Water Pollution Research Laboratory, D.S.I.R., 1958)) deals with the effect of organic discharge on the level of oxygen in a stream. It points out that information is particularly required on the rate at which rivers of different depths will absorb oxygen from the air and states that particular attention is to be given to the study of this property of rivers in the future programme of the Laboratory.

Animal Behaviour

The renewal of interest in the scientific study of animal behaviour, now generally known as ethology, which is one of the more remarkable features of the development of zoology in the past twenty-five years, has been marred by a lack of communication between the different schools of thought and between workers in different countries. This has given rise to a good many misunderstandings and needless arguments. In particular, the European school of behaviour students, who are mainly interested in the analysis of the more stereotyped kinds of behaviour of groups such as insects, birds and fish, were—partly as a result of the War—almost completely out of touch with the work of comparative psychologists (the 'rat psychologists') in the United States. These barriers have fortunately been falling rapidly in the past few years and there is now much less provincialism of outlook than there was. A welcome further step in the process of bringing two of these groups together is the metamorphosis of *The British Journal of Animal Behaviour* into a new journal to be entitled *Animal Behaviour*. This is the result of a liaison now established between the British members of the Association for the Study of Animal Behaviour, which was instituted in 1936 and published the original journal as the *Bulletin of Animal Behaviour* in 1938, and their American colleagues. This has resulted in a much enlarged journal, which is certainly necessary to cope with the great increase in papers in this subject, and will enable the editorial staff, which now includes American as well as British members, to accept additional American contributions without reducing the publication facilities which were available to the original members of the Association. It should also result in a greatly increased circulation. It is obvious from a perusal of the first volume of the new journal (which fortunately has not commenced re-numbering its volumes but is issued as Vol. 6, Nos. 1 and 2. Pp. 126 + 4 plates. Published twice yearly. Annual subscription 50*s.*; United States and Canada 8 dollars. London: Baillière, Tindall and Cox, Ltd., 1958) that it is the intention of the editors to maintain the existing high standard. The new venture should be warmly welcomed and given every encouragement.

Courses in Higher Technology

The London and Home Counties Regional Advisory Council for Higher Technological Education has produced a bulletin (Bulletin of Special Courses in Higher Technology, including Management Studies and Commerce, 1958–9, Part 1: Autumn Term. Pp. 122. (London: London and Home Counties Regional Advisory Council for Higher Technological Education, 1958.) 3*s.*) giving details of special advanced courses held in the London and Home Counties region which do not regularly appear in college calendars or prospectuses as part of a grouped course or as subjects offered for endorsement on Higher National Certificates. They are, as a rule, part-time (usually evening) courses, but full-time courses which are specially arranged and are not of longer than three months duration are also included. Sessional evening postgraduate courses leading to higher degrees in science (including mathematics) and engineering are not included in the Bulletin. Among the courses are macromolecular chemistry and structural design in aluminium at Battersea College of Technology; physical methods of assessing flour quality and pulse techniques at the Borough Polytechnic; applied ultrasonics at Brunel College of Technology; taxation case law at the City of London College; technical Russian at the Ewell County Technical College; and bacteriology for public health engineers at the Imperial College of Science and Technology.

The Night Sky in October

New moon occurs on Oct. 12d. 20h. 52m. U.T., and full moon on Oct. 27d. 15h. 41m. The following conjunctions with the Moon take place; Oct. 2d. 18h., Mars 2° N.; Oct. 17d. 01h., Saturn 3° S.; Oct. 29d. 19h., Mars 3° N. There will be a total eclipse of the Sun on October 12, invisible at Greenwich. Mercury is too close to the Sun for observation. Venus is a morning star, but is now unfavourably placed for observation. Mars rises at 19h. 40m., 18h. 45m. and 17h. 25m. at the beginning, middle and end of the month, respectively; it is visible throughout the night. Its stellar magnitude increases during the month from − 1·1 to − 1·8, its distance from the Earth decreasing from 56 to 46 million miles. Mars moves eastwards until October 9, when it reaches a stationary point. It is then between the Pleiades and the Hyades. After October 9, Mars begins to retrograde but it remains in Taurus throughout the month. Jupiter is too close to the Sun for observation. Saturn sets at 20h. 35m., 19h. 45m. and 18h. 50m. at the beginning, middle and end of the month, respectively; the planet may be visible for a short time low in the south-west after sunset, but conditions for observation are not favourable. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Oct. 3d. 03h. 16·6m., δ Tau. (*D*); Oct. 3d. 03h. 59·6m., δ Tau. (*R*); Oct. 3d. 05h. 00·8m., 64 Tau. (*R*); Oct. 8d. 03h. 15·1m., A^2 Cnc. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Orionid meteors are active during the third week of the month, conditions being moderately favourable; the radiant is near R.A. 6h. 24m., Dec. + 15°.

Announcements

Dr. Henry S. Odbert has been appointed programme director for psychobiology, Division of Biological and Medical Sciences, U.S. National Science Foundation. Dr. Odbert was formerly chief of the Occupational Analysis Branch of the Personnel Laboratory of the Wright Air Development Center, Lackland Air Force Base, Texas.

Dr. B. Cinader has resigned from the post of principal scientific officer in the Department of Experimental Pathology at the Agricultural Research Council Institute of Animal Physiology at Babraham, Cambridge, and has been appointed head of the Subdivision of Immunochemistry in the Ontario Cancer Institute and associate professor in the Department of Medical Biophysics of the University of Toronto (500 Sherbourne Street, Toronto 5).

The International Trust for Zoological Nomenclature announces that it has accepted with regret the resignation of Mr. Francis Hemming as a member of the Trust and as managing director and secretary. Lt.-Col. F. J. Griffin, who is an original member of the Trust, has been appointed managing director and secretary. Mr. R. V. Melville, who has been acting assistant manager, has been appointed scientific controller, with responsibility for the scientific and editorial work hitherto carried out by Mr. Hemming.

A symposium on "Batteries" will be held at the Signals Research and Development Establishment, Christchurch, Hants, during October 21–23. Further information can be obtained from the Organizer, Battery Symposium, at the above address.

The second Technical Convention of the Indian Institution of Telecommunication Engineers will be held in New Delhi on December 27 and 28, when papers will be read on the following subjects: antenna and wave propagation, broadcasting in India, tropicalization of communication equipment, semiconductors, telephone communication in India, navigational aids, atmospheric and radio noise. Papers intended for presentation at the Convention should preferably deal with original investigations or describe developmental work embodying novel features. The last date for the receipt of abstracts of proposed papers is October 15. Further details may be obtained from the Honorary Secretary, Institution of Telecommunication Engineers, Post Box No. 481, New Delhi.

Erratum. In the communication entitled "Dissociation of Serological Complexes of Ovalbumin and Hæmoglobin using Aqueous Carbon Dioxide", by Dr. B. T. Tozer, K. A. Cammack and Dr. H. Smith, published in *Nature* of September 6, p. 669, column 2, line 6 should read "confirmed by measurements of light absorption at 410 mμ", and not "confirmed by measurements of light at 410 mμ" as printed.

CONFERENCE ON PLANT BREEDING

THE eighth Plant Breeders' Conference was held at the Welsh Plant Breeding Station, Aberystwyth, on July 2 and 3. Participants included representatives of nine research stations in the United Kingdom together with representatives of universities and other institutions at home and abroad.

Members of the Welsh Plant Breeding Station and also Mr. J. L. Fyfe of the Plant Breeding Institute, Cambridge, opened discussions on problems relating to the breeding and assessment of grasses, clovers, cereals and field beans.

Mr. Elfed J. Lewis described an experiment designed to assess, by means of a diallel cross, the potential breeding value of plants selected from an outbreeding species (perennial rye-grass). The data were analysed to determine the usefulness of the diallel technique as a rapid means of obtaining the information required.

It was found that increase in hay and aftermath production showed high average dominance, uncomplicated by non-allelic interaction, indicating that there was no specific combining ability among the plants involved. This implies that improvement could be achieved by the accumulation of favourable dominant alleles, and this is borne out by the fact that the plants from the improved strains show a relatively higher degree of homozygosity for the dominant genes giving favourable expression.

During the discussion it was emphasized that the high degree of homozygosity shown in plants from certain of the bred strains did not necessarily mean that these plants were homozygous for all genes, but rather for those genes by which the plants involved differed, and that the information derived was heavily weighted with regard to the degree of dominance exhibited.

The genetics of production characters in rye-grass were dealt with by Dr. J. P. Cooper, who stressed the importance of three parameters: the amount of genetic variation available, its accuracy of measurement and its heritability. Estimates of these parameters had been obtained for several agronomic characters in local and bred strains of rye-grass.

Heading behaviour had been subjected to the most detailed study; the data for replicated clones showed little variation between blocks within one year, and high repeatability between years. Heritability was also high and most of the genetic variation is additive, but all plants were heterozygous for genes controlling date of heading, and a small group of plants of similar phenotype could carry much potential genetic variation.

Pilot studies indicate that length of leaf and rate of leaf appearance were highly heritable, but this was less marked for the rate of tillering. Italian rye-grass and both Irish and *S*23 perennial rye-grass contain appreciable additive genetic variation for these components, and response to selection should thus be possible. Most plants are highly heterozygous for genes controlling these vegetative characters.

Dr. Keith Jones dealt with the cytological basis for interspecific hybridization in cocksfoot breeding. A classification has been made of a wide range of material into diploids ($2n = 14$) and tetraploids ($2n = 28$) and the extent of aneuploidy was determined. No appreciable chromosomal differentiation was found between diploids and tetraploids or between different tetraploids. It now seems quite possible to combine genes from diploids and tetraploids, for when triploids were crossed with either diploids or tetraploids the most common progeny types had the same chromosome number as the male parent, and chromosome pairing in them was complete and stable.

Dr. M. Borrill showed that the diploid subspecies had a restricted geographical distribution and that they intercrossed freely and produced fertile hybrids. Similarly the geographical races of tetraploids had produced fertile hybrids. As the extensive genic differentiation had not reduced hybrid fertility, any potentially useful genetic type could be utilized by the breeder; for example, a diploid from Portugal and some Mediterranean races which have winter green growth and desirable foliar characteristics.

Mr. W. Ellis Davies read a paper on the number of plants required as the basis of a strain of red clover. Sixteen experimental strains had been produced from a population of Montgomery red clover; they were based on 3, 6 or 12 plants taken at random, with a control based on 200 plants. The control strain gave a similar yield from the second to the fifth generation; the other strains showed an average decrease in yield of green matter, but this was due largely to the strains based on three plants. One of the latter strains yielded 50 per cent above control in the second generation but it showed a rapid decrease thereafter. When the number of plants in the base of the strain is increased the mean yield approximates the control. On the other hand, evidence was produced showing that improvement could be effected by restricting the base to a limited number of superior plants.

Mr. J. L. Fyfe spoke on the evaluation of inbred lines of lucerne; his data on single crosses between second inbreds showed that reciprocal differences were negligible and that contributions made by specific combining ability are usually not statistically significant; inferior lines could be eliminated by tests of general combining ability. A linear relation appears to exist between yield and inbreeding coefficient, which should be considered in comparing single-cross or test-cross with double-cross performance.

The use of polyploidy and species hybridization in the breeding of forage legumes was discussed by Dr. Alice M. Evans. Her results showed that induced polyploidy in *Trifolium pratense*, *T. repens* and *Medicago sativa* could produce higher yields and that reduced fertility could largely be restored by continued selection. By using some of the newer techniques, a few species of *Trifolium* were found capable of inter-hybridization and thus the introduction of new genes into these species had become possible.

Mr. Ll. Iorwerth Jones presented data to show that the height of cutting when sampling herbage plants with different habits of growth affected the assessment of their yield and that the management practised affected the subsequent production of the swards based on different strains of a species. It was impossible to obtain one assessment figure to express the value of a strain relative to another when tested under different conditions; trials involving grazing had given different results from those based on cutting.

An outline of the problems of introducing new variability into cultivated oats through 6× amphidiploids and the induction of mutations was given by Dr. D. J. Griffiths. With the view of introducing genetic factors such as disease resistance into cultivated hexaploid varieties, experimental 6× amphidiploids had been produced through crossing tetraploid with diploid species followed by colchicine treatment. Representative plants from A_2 and A_3 generations of 6× amphidiploids developed from *A. barbata* × *A. strigosa* subsp. *hirtula* had been crossed with natural hexaploid species as well as with other amphidiploids. The data produced on disease reactions, fertility and morphological characteristics of the F_1 generations were discussed in relation to practical breeding.

In his paper on problems of selecting for yield in oats Mr. J. D. Hayes indicated that improvements had been achieved by concentrating on major factors limiting yields such as straw length and disease reaction. Further improvement must, however, be based on increase in yield of grain, and tests capable of detecting differences of 10 per cent or less are required. A large number of replications were required at present to achieve this precision, but the error variance could be reduced in various ways. Some problems associated with early generation testing were raised; it was suggested that the area of land used for this test should be greatly increased.

Dr. D. G. Rowlands had found that *Vicia faba* showed cytological irregularities of a type normally associated with the inbreeding of a naturally outbreeding species; this was confirmed by controlled pollination experiments. The existence of both cross- and self-sterility has been found; inbreeding resulted in reduced pod and seed formation as well as in many sterile plants, but occasional plants produced pods and seeds satisfactorily. Although hybrid populations had shown consistent superiority over inbreds, long-term improvement of field beans must be sought through the development of self-fertile lines; in the meantime improvement in yield may be possible by producing synthetic varieties.

Informal discussions were continued during the afternoons at demonstrations of the work of the Station in the breeding grounds, greenhouses and laboratories of the new headquarters, Gogerddan, near Aberystwyth.

Lolium multiflorum × *Festuca arundinacea* derivatives in which fertility had been restored by doubling the chromosome number were demonstrated. Several potential strains of grasses bred for the colder months when grass is normally scarce were shown as well as the wide range of diploid and tetraploid ecotypes of *Dactylis*. The work in cytology included investigations of inter- and intra-specific relationships of grasses and cytological surveys of field populations. The laboratory techniques for uncovering genetic variation in *Lolium* and *Phleum* under controlled photoperiod and temperature were illustrated and also the application of this rapid technique for strain identification. The herbage legume breeding programme included the production of higher-yielding, late-flowering red clover, larger-leaved and more persistent types of white clover and lucerne for high rainfall areas. Studies on the inheritance of flower colour in lucerne and lucerne selections for tolerance to manganese deficiency were demonstrated.

In the work on oats, emphasis was laid on improvement of yields for different levels of fertility, resistance to stem eelworm and mildew and the use of irradiation for improvement of winter varieties. The value of diallel crossing for barley and wheat breeding was under investigation. Improvement in yields and early ripening was sought in field beans. In the rape crop the chief aims were improvement in frost resistance and leafiness; the effect of hybridization on plant vigour was shown.

Studies of agronomic techniques for the assessment of herbage strains were seen and also agronomic studies of potential strains of grasses. The effects of management of grasses grown in wide drills and as clones on the subsequent seed crops were under investigation and also the effect of density on grass seed yields. Gibberellic acid was used in seed-production studies of late-flowering red clover. Routine laboratory determinations of fibre and nitrogen contents are made for the breeders and agronomists and investigations of soil nutrients are in progress.

GWILYM EVANS

THE MACAULAY INSTITUTE FOR SOIL RESEARCH

THE main body of the annual report (1956–57) of the Macaulay Institute for Soil Research, Aberdeen (pp. 66; from the Institute at Craigiebuckler, Aberdeen; 1958), is devoted to the work of the Pedology Department. The soil survey of the country around Banff, Huntly and Turriff, Jedburgh and Morebattle, and Kilmarnock has been completed. The typical horizons of the seven major soil groups so far encountered are listed. (Full details will be found in the three appropriate memoirs published by the Soil Survey of Scotland.) Other sections of the Pedology Department contribute to the ecology of peat pollen analysis and Quaternary research, bog cultivation and reclamation, studies on Scottish soils, problems of phosphate fixation, rock weathering, the application of differential thermal analysis to clay mineralogy, etc.

The Department of Spectrochemistry has done collaborative work on trace elements in addition to the investigation of spectrochemical methods of analysis concerning flame, arc, spark and pulsed arc emission. Differences in the infra-red absorption spectra of di- and tri-octahedral clay minerals as well as smaller differences between individual minerals in each group have been observed. Infra-red spectrometry has also been applied to the identification of organic compounds in microbial metabolism. Modification of absorption spectra are described due to the presence of bases in alcohols and sodium ions in potassium bromide in ultra-violet and infra-red spectrometry.

The work of the Biochemistry Department embraces: the lignin derivatives, carbohydrates and amino-acids in soils and peats; the metabolism of soil micro-organisms in relation to the biological synthesis of 6-O-acetyl-D-glucopyranose and acetyl-glucose, and the β-oxidation of aliphatic hydrocarbons and herbicidal fatty acids; and the determination of the organic acids, amino-acids and water-soluble carbohydrates in plants. A short note on special methods is also included.

The Plant Physiology Department reports work on mineral balance principally (including major element interaction and the NO_3^- : $NH_4^{\cdot}$ effect). Respiration studies include the sensitivity of dwarf shoots of larch and cedar to potassium cyanide and the metabolism of disks of storage tissue. Measurements of the cation exchange capacity of roots under toxic levels of various metals are described. The influence of fission products fall-out on the extraneous radioactivity in samples of vegetation has also been examined.

The Department of Soil Fertility has been mainly concerned with interrelated field, pot and laboratory work on crop responses (to the major nutrients, the trace elements and magnesium) of different crops grown on the major soil types, and the distribution, composition and stability of nucleic acids in the soil organic phosphorus. In addition to collaborative work on soil micro-organisms described earlier, the Microbiology Department has investigated the growth of thermophilic actinomycetes from composts and the demethoxylation of simple aromatic compounds by soil fungi and wood-rotting basidiomycetes. A preliminary report on the role of micro-organisms of the root region in the phosphate nutrition of plants is given.

Brief accounts from the Forestry, Radioactivity and Statistics Sections are also included.

AGRICULTURAL HISTORY IN HOLLAND

In England the study of agricultural history is in the main a discipline that forms part of the departments of economic history in our various universities. For the past five years it has also been stimulated by the founding of the Agricultural History Society. This Society was established by private enterprise, but as it numbers among its members many university personnel from all over the country, and indeed foreign countries, it has intimate relations with the academic institutions where the subject is being studied.

It is of the greatest importance in Holland, where the progress of farming has been an example and a lesson to other European countries, England in particular. In 1939 a Studiekring voor de Geschiedenis van de Landbouw was privately organized as a Department of the Koninklijk Genootschap voor Landbouwwetenschap, with headquarters at Wageningen. This Studiekring includes Belgian members as well as Dutch. It has published four volumes at intervals since its formation.

Enthusiasm for the subject waxed after the War, and led to the establishment of the Nederlands Agronomisch-Historisch Instituut: Instituut voor Landbouwgeschiedenis at Groningen. This Institute is financed jointly by the Dutch Ministry of Agriculture, the Farmers' Society, the Workers' Unions and the State University of Groningen. It is part of the academic world, and is now directed by Dr. L. S. Meihuizen. Its main work is the preparation of an annual international bibliography of current books, articles and original documents, under the title "Historia Agriculturae". The fourth volume of this publication was issued early in the current year. In addition to the bibliography, records and other important sources for Dutch agricultural history are printed in each volume. Besides this the Institute undertakes the supply of information regarding sources to students and scholars both in the Netherlands and in other countries. To facilitate this work the Institute has collected a considerable and growing library of international works and prepared an extensive documentation. When agricultural archives come to its notice the Institute arranges, when possible, for them to be deposited in the State Archive Library, where they are cared for by the Keeper of State Archives.

In addition to the "Historia Agriculturae" other work currently being undertaken at the Institute is: (*a*) the collection of sixteenth- and seventeenth-century notices of orders issued by the local authorities for the regulation of farming and the marketing of produce; (*b*) a bibliography covering the life and conditions of employment of the Dutch farm worker; (*c*) a study of the economic history of the trade in farm produce in a polder in Zeeland in the nineteenth century. A hand-list of sources for Dutch students of agricultural history is in preparation.

Last year the organization of agricultural history was strengthened by the establishment of a Department of Agricultural History at the Landbouwhogeschool at Wageningen under the direction of Prof. B. H. Slicher van Bath, formerly professor in the State University at Groningen. He will be responsible for a course in agricultural history for undergraduates, and is directing research in the social and economic history of farming in Holland. In this connexion he is editing a series of studies "Historische Sociografieën van het Platteland", the first volume of which, "Een Samenleving onder Spanning: Geschiedenis van het Platteland in Overijssel", appeared last year over his own signature. He continues to act as secretary to the directing board of the Groningen Institute.

A further activity of this Department will be the reorganization of the Agricultural Museum at Wageningen on modern museum lines and its expansion to make it the repository of a collection of early agricultural equipment, implements and tools, and form an adequate instrument for the preservation and study of such things. This work is being done by Dr. J. M. G. van der Poel, formerly director of the Groningen Institute, whose reputation is already known beyond the frontiers of Holland, and who has formulated an imposing plan for the future.

Clearly the Dutch have recognized the importance of the study of agricultural history—both the academic world, the government, and the industry itself.

G. E. Fussell

OPERATIONAL RESEARCH IN ADVERTISING

RESEARCH into advertising has been much intensified in recent years, and it is timely to find that a paper on the subject has been read by Mr. J. Maitland at this year's meeting of Section F (Economics) of the British Association.

The problem studied may be very simply stated. It is to determine the relationship, if any, between the amount of advertising (concerning some article or service) and the response to it. It is supposed that the problem of defining measures of the 'amount of advertising' and the 'response' has been settled previously. Advertising is considered as an example of a stimulus; this stimulus is regarded as the input, and the response as the output. Thus we have an input–output situation of the type well known in experimental psychology, and this leads to a model based on a physiological analogy. Data were taken from five sets of advertising campaigns: (1) advertisement, by way of technical journal announcements and leaflets mailed to medical practitioners, of a vitamin product; (2) mailed leaflets based on the membership lists of learned societies and professional organizations; (3) service recruiting by means of newspaper advertisements, type 1; (4) as in (3), type 2; (5) radio equipment advertised in daily newspapers. The amount of advertising, A, was measured in terms of quantities such as the number of announcements or journal issues or leaflets distributed, while the response, R, was measured in terms of the number of inquiries.

In order to set up a model of the input–output system, three analogies were used—physiological, biological assay and physical.

Physiological analogy. In this case a linear relationship between R and $\ln A$ would be expected. By plotting the data referred to above such a relationship was reasonably suggested. The method of least squares was used in fitting the curve. The linear relationship, $R = a \ln A + b$, where a and b are constants, suggested that: (1) there is a threshold value of advertising below which there is no appreciable response; (2) as the amount of advertising increases a state of saturation is reached in the sense that further advertising produces a negligible response.

These results permit an estimation of the point at which the marginal gain becomes too small to justify increased advertising.

An alternative formulation is in terms of the law of diminishing returns (see Zentler and Ryde, *Management Science*, 2, 337; 1956) and it is found that the response R may be related to the expenditure, x, on promotion by an equation of the form:

$$R = R'y^2/(1 + y + y^2)$$

where $y = x/b$ and R' and b are constants.

The analogy of biological assay. This is the model to use if one is interested in relative rather than absolute response. The numerical data available were analysed to determine the increase in the proportion of the population responding to a prescribed increase in the amount of advertising.

Physical analogy. Here reference is made to the work of Vidale and Wolfe (*Operations Research*, 5, 370; 1957), who introduced the concept of a saturation-level as the practical limit of sales that may be generated as promotional activity is increased in intensity. The mathematics of this case leads to an equation which implies an exponential rise of R to a maximum as advertising intensity is increased. Thus the analogy is that of the charging of an electrical condenser.

The proportions of the population responding to varying degrees of stimulus are compared for the various methods used. There is little difference between the results obtained by the logarithmic law and by the probit analysis, although the former involves less computation. The simplest form of the theory of Zentler and Ryde is not very satisfactory, and a more complex form is inconvenient in comparison with the other alternatives.

ATOMIC POWER IN CANADA

DURING the Second World War, Chalk River, Ontario, was selected by the Canadian Atomic Energy Project as the site for the major research reactor, NRX, which was to be a high-flux reactor fuelled with natural uranium metal, moderated with heavy water and cooled with natural water. The low-energy heavy-water reactor, ZEEP, was first constructed on the site in 1945 and this served as a check on the design of NRX. In 1947, NRX began to operate with a heat output of 30 megawatts. A more powerful reactor, NRU, fuelled with natural uranium metal but both cooled and moderated with heavy water, was then constructed on the site, and this came into operation in 1957 at 200 megawatts. Like NRX, NRU was designed to take advantage of the high neutron flux produced for the production of plutonium and radioactive isotopes for research purposes, but both reactors operate at low temperature and pressure, and in neither is it possible to employ usefully the heat produced.

An increasing proportion of the research and development work at Chalk River was, however, devoted from 1951 onwards to problems related to the provision of economic atomic power, and although direct progress was somewhat slowed down by the accident which occurred to the NRX reactor in December 1952, the successful reconstruction of the reactor and its power increase to 40 megawatts brought valuable confidence in the long-term maintenance and the safety of heavy-water moderated reactors for power. The use of heavy water leads to good economy of neutrons and is one of the best long-term prospects for cheap nuclear power. The gas-cooled, graphite-moderated reactors in use in Great Britain required less development work and, therefore, were brought into operation sooner, but the price at which they produce electricity is for most places in Canada much too high to compete with other available sources of electricity.

Early in 1954 a group, known as the Nuclear Power Branch, was set up in Chalk River to study the design of nuclear reactors for the economic production of power, and a demonstration reactor, known as NPD-2 and proposed by the Branch, is now under construction by the Canadian General Electric Company at Des Joachims on the Ottawa River and is expected to come into operation during 1961. In September 1955, after the decision had been taken to build NPD, the Branch began a study of a full-scale nuclear plant. The results of this study were described in a report in May 1957, but which was given only limited circulation.

However, a booklet* based on the report, giving the background history of the Canadian project and describing in detail the plant designed by the Nuclear Power Branch, has been prepared by J. E. Woolston and has recently been issued. In the first two sections the possible demand for nuclear power in Canada and the general approach to the study including the cost target for a competitive nuclear power plant are discussed. The third section deals in detail with the proposed reactor, which has a thermal power of 794 megawatts and a net electrical output of 200 megawatts. Slugs of natural uranium oxide are used as fuel, and it is cooled and moderated by heavy water. The fuel is housed in horizontal pressure tubes through which the pressurized heavy-water coolant passes. There are 200–250 tubes mounted on a square-lattice with a pitch of one foot. A feature of the design is the high burn-up planned for the unenriched oxide, which is considered to be of greater economic advantage than the improvement of the steam conditions and the rather poor thermal efficiency of the plant. The final sections in the report deal with the range of studies carried out by the Branch and the alternative systems investigated; pertinent Chalk River experience; and the estimate of cost of the nuclear plant and its operation. The names of the members of the staff of the Nuclear Power Branch who participated in the studies leading to the proposed reactor are listed in one appendix, and in another complete data on the main components of the reactor are set out.

RESEARCH IN ALBERTA

THE thirty-eighth annual report of the Research Council of Alberta* records generally satisfactory progress in all projects during the calendar year 1957 and also in the recruitment of staff of high calibre. A feature of the year was the development of the geological research and survey operations which led to the initiation of survey operations in the north-east corner of Alberta in the Precambrian Shield area. The expansion of the co-operative basic cloud physics research programme with particular reference to the problem of hail in Western Canada was also noteworthy. In the work on coal, evidence was obtained that the calorific value decreases considerably when coals were exposed to the air for prolonged periods, and the thermograms of several coal fractions and of three dated fossil woods were determined. In other differential thermal analysis studies it was observed that sulphur dioxide can modify extensively the course of the pyrolysis of coal. A study of the grindability of coal was completed, and considerable progress made in studies of fluidized coal carbonization.

A theoretical analysis of the flow of stratified water and oil in horizontal pipe-lines agreed well with experimental observations, and progress is reported in the catalytic desulphurization and oxidation with nitric acid of organic sulphur compounds. The study of detailed trace metal and component geochemistry of four major and several minor oilfields was completed; engineering studies continued on the high-temperature pyrolysis of natural gas and a process was developed for removing nitrogen from natural gas. An infiltration study on a river terrace south of Camrose indicated that certain surface water supplies in Alberta can be purified by this technique. Results obtained in studies on electrosomatic flow into clay soils provide a starting point for computing the power requirements necessary to reduce the moisture content of soil by this method, and besides work on the strength, stability and compaction of a base cover material, the instability conditions in bridge abutments were investigated and the problem of frost action received continued attention.

The biological cycles programme, which was brought to a virtual close by the death of Dr. W. Rowan, has indicated a rather dramatic increase in grouse and rabbit populations in many areas. Studies on the nutritive value of rape-seed oil indicate that fermenting and drying ground rape-seed prior to oil extraction remove two of the toxic factors and that the high temperatures used in extracting the oil may be partly responsible for the varying feeding value of commercial rape-seed oil meals. The adsorption areas of acetylene, ethylene and ethane on Charcoal No. 2222 have been measured, and it appears that the less 'active', finer-pored charcoal may be more valuable for certain dynamic separations of gases, as in chromatographic column, a technique which is proving of increasing value. A weather radar set has been installed at Penhold and used to follow the detailed courses of precipitating storms within 100 miles, while the hail-reporting network now covers some 15,000 square miles in central Alberta. Lapse-time cloud photography was also expanded and the commercial hail-suppression programme operated over 400 square miles in the southern part of the hail project area. Ground-water conditions were surveyed in five districts and the answering of inquiries is an important part of the ground-water programme. The palæobotanical laboratory continued to be concerned chiefly with describing and cataloguing the Edmonton Paskapoo fossil floras in central Alberta, and microslides have now been made of all the species of modern conifer woods in the type collection. A list of publications is appended.

THE ONTARIO RESEARCH FOUNDATION

THE report of the Ontario Research Foundation for 1957*, which includes a list of papers published during the year, records a slight excess of income over expenditure—33,958 dollars over an expenditure of 1,248,421 dollars, but the Director in his introductory report refers to the curtailment of basic research because the sum available has remained stationary over the past ten years. Additional support has now been requested from the Ontario Government.

In biochemistry, work on the development of tanning materials from waste sulphite liquor has shown that sole leather can be tanned with a phenol condensate in pilot-scale experiments, and large-scale commercial trials are necessary to determine the economics of the process. By impregnating sole leather with mixtures of synthetic resins and plasticizers its rating on an abrasion test machine was increased by 200 per cent, but the result was not confirmed in wear tests on shoes. An edible spread from Canadian edible oils which could be spread at −10° F. and did not 'oil off' at 100° F. was very satisfactory on pilot plant tests, and very encouraging techniques have been developed for separating amino-acids from commercial protein hydrolysates.

Encouraging growth in sponsored research is reported in the Chemistry Department, and three new fellowships were initiated in the Wood Chemistry Section. Studies of the *iso*propyl alcohol extract of waste sulphite liquor and the residual aqueous fraction yielded a new tanning material, and a phenolated high-molecular weight lignin fraction was superior in dispersing properties to the quebracho used in lime-base oil-drilling muds and increased the fluidity of wet concrete. A study of the kinetics of crystallization of calcium sulphate dihydrate from supersaturated solutions showed that, after an initial nucleation period, the process followed first-order kinetics, the rate constant depending on the initial degree of supersaturation. Significant differences have been demonstrated in the corrosion resistance of a Watts nickel deposit as a result of various methods of polishing the steel. A complete revision of the paper chromatographic techniques reduced the errors in analysing phosphate glasses for structural components to those associated with cutting the chromatogram to separate the polymers.

In the Department of Engineering and Metallurgy three new sponsored fellowships were initiated, including one to study the oxidation of nickel at high temperatures. The study of the fundamental fatigue of metals continued with the view of detecting signs of elementary strain or damage during tensile or fatigue loading. Brittle fatigue is being studied with a special jig developed for the purpose and steels for high-temperature service incorporating non-metallic materials by a new design of creep extensometer. High-strength steels of good tensile properties have been produced by rapid heat-treatment methods. In the Ferrous Metallurgy Section hæmatite has been converted to magnetite by flash roasting and magnetite reduced to metallic iron in the jet smelter. The Department of Mathematical Statistics examined sampling procedures for the Bureau of Broadcast Measurement, surveyed the fuel consumption of trucks and buses for the Ontario Department of Transport and continued an extensive programme on sizing systems for garments in co-operation with the Textiles Department, where a satisfactory technique has been developed for measuring the modulus of rigidity of a wool fibre immersed in a liquid, which gives a sensitive means of following changes in physical properties caused by chemical processes. A long-term study was completed of methods for stabilizing viscose rayon fabrics against dimensional changes in laundering.

The work of blood parasites of birds continued with promising results, attention being concentrated on two, *Leucocytozoon* and *Haemoproteus*, which invade the red corpuscles, and the data accumulated show that different kinds of birds have distinctly different types of parasite. A microscopic study of the fine sands from samples of horizons from selected soil profiles was started, and observations regarding evaporation from small plots of grass on moist soil were again taken daily at Norman Hills and at Kapuskasing on the Dominion Experimental Farm.

SUPPORT AND DIRECTION OF RESEARCH AT AMERICAN ACADEMIC INSTITUTIONS

IN a symposium on "The Changing Patterns of Academic Research", which had been organized by Sigma Xi, Dr. Lloyd V. Berkner, president of Associated Universities Inc., discussed the support and direction of research at academic institutions in the United States (*Amer. Sci.*, 46, No. 2 ; June 1958). He first examined the direction and balance of effort that is likely to produce the most significant advances to human knowledge. Research problems tend to be in competition among themselves for support, and a single large research effort may involve funds that could generate a great many research efforts on a smaller scale. In management of research, therefore, one is faced with advance assessment of the significance of a large effort in contrast to the integrated significance of a number of smaller efforts which that large effort potentially represents. Having defined research as having goals beyond the limits of human knowledge, it is apparent that such decisions in allocation of research-support require a 'crystal ball'.

Berkner arbitrarily divided research activities according to the size of the effort involved as follows : (1) conventional research on an individual scale involving essentially 'string and sealing wax techniques' or corresponding theoretical activity ; (2) group research in a particular area or discipline of science involving modest tools; (3) group research of an interdisciplinary character involving the synthesis of ideas from many branches of science; and (4) research involving major and expensive tools, or very large and expensive group efforts.

That persons best suited to individual research are most often found in the faculties of the colleges and universities is no accident. The diversity of the university atmosphere can react to broaden the interest of the individual and provide the intellectual tools required to associate diverse facts. But support of qualified individual effort must not be restricted to the university; such effort should be nurtured in whatever atmosphere suitable minds are found.

The growing complexity of ideas and the problems of assembly and operation of even modest experimental apparatus has brought group research ever more into the forefront. Experience shows that four to seven workers devoting their effort to a single problem appear to react together in a kind of optimum way in advancing scientific knowledge. Usually, such a group operates under the motivation of an intellectually strong leader with a number of associates each carrying part of the load. Very often such a team will require the use of large and expensive research tools operated by someone else to provide them with the means for their success. But the core of the effort is the small team—men who work together as equals in the assembly and perfection of their apparatus, and in ordering facts and ideas to achieve the final solution. The group effort in the discovery of the anti-proton or the anti-neutron, or the direct proof of the existence of the neutrino, may be cited as examples of the need for, and effectiveness of, group effort.

Then there is the direction of research toward goals involving large and expensive tools or highly organized efforts. In the study of the macrocosm, the universe, the microcosm and the atom, large and expensive tools are necessary to order and to convey the phenomena to our simple senses. Even in the study of the Earth itself, highly organized and extensive efforts of thousands of scientists over its surface are necessary to provide a scientific view of the Earth as a planet.

In the administration of research, leaders are constantly faced with the dilemma of deciding the proper division of funds between the large-scale research devices as contrasted with the individual or group research efforts. The decision to expend effort and support on large research tools must rest upon the evaluation of the contribution that the tool can make to the sum of human knowledge. Without such tools, science cannot be provided with the essential information on which even the individual research worker must depend to keep his thinking tied to reality. The recent destruction of the generality of the concept of parity has clearly emerged from the development of ideas arising from research with the great nuclear accelerators. Where this new concept will lead, that Nature discriminates between right- and left-handed motion, no one at the moment can say.

The effectiveness of the individual worker depends on a balanced progress of human thought in every field, even though some fields of research require tools that are disproportionately expensive. Without support for the sciences that require expensive apparatus or effort, the whole of science would soon become over-specialized and sterile. The problem is to achieve balance between the support of the small research worker and the provision of adequate tools required for the significant advancement of scientific progress on every front.

This problem of balance becomes especially important when progress in one science becomes noticeably limited by lack of effort in the related sciences. From a recent study on the progress of meteorology, it seems apparent that a limiting factor in the growth of meteorological science is the slower progress in our knowledge of the oceans and the absence of development of synoptic oceanography.

Perhaps critical dependence on costly scientific tools or operations may best be dramatized by citing the example of the Earth satellite. The instrumentation, launching, tracking, and data-collection involved in the satellite programme are very expensive, involving some tens of millions of dollars. Concern has been expressed that the equivalent sum of money directed toward other research objectives might be more effective. But this concern seems open to question when one examines the potentialities of the satellite as a new and fundamental scientific tool that provides a power of a new order of magnitude to science. The satellite offers the opportunity of measuring for the first time the heat balance of the Earth. The satellite can provide a knowledge of the external size distribution, density and variation of meteoric dust—particles that may conceivably provide condensation nuclei as an external environmental influence on cloud formation and rainfall. It can describe variations in the solar, ultra-violet and X-radiations from a vantage-point above the absorbing atmosphere that is influenced by such radiation and vastly extend our power for study of the Sun itself. The satellite can eventually map the complex of cloud and storm systems and their movement over the entire surface of the Earth, including 75 per cent of the area over the oceans and the polar regions that now are instrumentally inaccessible.

In addition, the satellite will acquire information concerning a whole range of other scientific phenomena such as the primary cosmic ray spectrum, before it enters the atmosphere, and the magnetic field of the Earth in its extensions and distortions in space. As a new major tool in science, the very large expenditures required for the erection of the satellite may turn whole areas of individual or group research into entirely new and more productive avenues.

Turning to the problem of support for research, Berkner suggested that the most desirable form should originate from a diversity of sources. The problem is to encourage and justify support from the wide range of agencies which in our society benefit from the advancement of scientific thought. First of all, the universities themselves have a responsibility to provide support for research activities within their bounds. Second, a great growth of industrial support must be generated. Ultimately something like one per cent of the gross output of American industry should be made available to the universities and related academic activities for pure research as distinguished from their educational effort. In addition to the support of their own large research laboratories that both contribute to, and capitalize on, scientific progress, industry must carry an additional burden of responsibility to make possible the growth of fundamental thought that can only emerge from the university.

There was a time in human history when the motivation for scientific research was purely the curiosity of man and his aspiration to know the nature of things around. To-day there is another compelling challenge that motivates research—as society has acquired the benefits of science, it has become wholly dependent on the continual production of new benefits from science so that the motivation for research is no longer wholly academic.

At the present time, as nearly as can be estimated, the money expended in the United States for fundamental research based on studies is approximately two hundred million dollars annually from all sources, government and private. This is approximately five-hundredths of one per cent of the gross national product. In the future the economic development of the country must depend more and more upon new resources and capital developed from man's brain rather than from his brawn. Perhaps on this idea one can estimate that it is not unreasonable that the total national fundamental research effort should be pushed to an annual level of perhaps one half of one per cent of the gross national product.

THE PHYSICAL SOCIETY

At the annual general meeting of the Physical Society, held in London at the offices of the Society on May 30, the reports of the Council and of the honorary treasurer and the accounts and balance sheet for 1957 were presented and adopted, and the officers and Council for 1958–59 were elected (see *Nature*, 181, 1640; 1958). Immediately prior to the annual meeting an extraordinary general meeting was held to give approval to an alteration of the rules of the Society whereby the status of honorary exhibition secretary was raised to that of honorary secretary of the Society. In the newly elected council Mr. A. G. Peacock becomes the first honorary secretary (exhibition), joining the two other honorary secretaries, Dr. H. H. Hopkins (papers) and Dr. C. G. Wynne (business), who were re-elected.

The accounts show that the total income of the Society was £49,075, comprising £5,747 from membership subscription, £25,969 from publications, and £17,359 from the forty-first exhibition of scientific instruments and apparatus which was held during March 25–28, 1957, in the Old and New Halls of the Royal Horticultural Society, London. The excess of income over expenditure, merely £20, was very much less than in recent years, and two reasons are advanced for this reduction—a decrease of £1,000 in the annual grant received from the Royal Society for publications and an abnormal increase, both in size and in the number of copies printed, of the 1957 issue (Vol. 20) of the *Reports on Progress in Physics* published by the Physical Society. It is expected that the Council's decision to increase the price of the Society's publications when sold to the general public will restore a more favourable financial position during 1958.

The Council's report refers only briefly to the activities of the Society and of its four specialist groups—Colour, Optical, Low Temperature and Acoustics—but it mentions that a more detailed list of the conferences, meetings and lectures which have been held is given in the 1957 Yearbook of the Society (*Nature*, 181, 1046; 1958). This list, however, covers the period September 1956–July 1957 and not the calendar year 1957, which is the period covered by the annual report.

In the section of the annual report dealing with the Society's publications it is stated that greater promptitude in publication of the *Proceedings* was achieved during the period under review. 199 papers, 68 research notes and 27 letters to the editor were published; 58 manuscripts were either rejected or withdrawn. It was decided to discontinue at the end of 1957 the sub-division of the *Proceedings* into the two sections, Parts *A* and *B*. Vol. 20 of the *Reports on Progress in Physics*, which was published during the summer, contains, in addition to nine reports, a cumulative index to the contents of Vols. 16–20, and both the index and individual reports are also available for purchase as separate pamphlets. No special publications or conference reports were issued during the year. S. Weintroub

FOOD ADDITIVES

The Joint FAO/WHO Expert Committee on Food Additives has now published its second report*. Whereas the first one dealt with general principles governing the use of such additives, this second report gives guidance on "Procedures for the testing of intentional food additives to establish their safety for use".

The use of food additives has greatly increased in recent years, and little is known about the health hazards which may result from their continual ingestion, either singly or in the mixture which a modern diet now provides. The Committee envisages the need for long-term animal feeding experiments since "the toxic or other biological effects of the test material cannot be predicted solely from a consideration of its chemical and physical properties". This is partly because a deleterious effect might be due not to the additive directly but to its effect on some other substance in the food or to changes consequent upon cooking, long storage, etc. Moreover, the same substance might exert a different effect when added to different foods, when fed to different age-groups, or when used in the diets of communities with different disease patterns. Since the hazard to the consumer will result from the total number of additives in the diet eaten, it is also necessary to have up-to-date information about the diets used by different groups within the community on whose behalf legislation is envisaged. The resultant effect of interplay between different additives may well vary with variations in the mixture of foods used to form the basic diet.

---

* Procedures for the Testing of Intentional Food Additives to establish their Safety for Use. Second Report of the Joint FAO/WHO Expert Committee on Food Additives. World Health Organization Technical Report Series No. 144. (Geneva, 1958.)

The Committee points out that the procedures outlined in the report require all the resources of a well-equipped laboratory and animal house, and an adequately trained staff "having access to current scientific literature over a wide field", and the warning is given that "the provision of such facilities on an adequate scale is very costly". Not all Governments could afford the outlay even if they had competent staff available for the work: yet the use of such additives without prior testing exposes the public to new risks of unknown magnitude, and protective legislation is undoubtedly required. Perhaps the difficulties involved will result in a reduction of the number of additives now used and a more emphatic application of the Committee's principle that "when a new food additive is proposed for use, clear evidence must be available to show that benefits to the consumer will ensue". The Committee also expresses the opinion that "no proved carcinogen should be considered suitable for use . . . in any amount".

M. W. GRANT

A NEW TYPE OF TITANIUM GETTER PUMP

By L. HOLLAND, L. LAURENSON and J. T. HOLDEN

Research Laboratory, Edwards High Vacuum, Ltd.

HERB *et al.*[1] have described a novel vacuum pump in which gas is absorbed by a freshly evaporated titanium film. Gases which were not easily absorbed by the getter were removed by ion pumping and such combined devices have been termed 'evapor-ion' pumps. The evaporation of titanium is rendered difficult because at the evaporation temperature the molten metal reacts readily with refractory materials. In the pump described by Davis and Divatia[2] titanium wire was fed on an electron-bombarded anode made of carbon which was replaced in later experiments by a tantalum–tungsten alloy. The useful life of these materials is limited, and the feed rate of the wire must be restricted to some 5 mgm./min. It is natural, therefore, that attention should be given to designs of vapour sources in which refractory supports are avoided, and some recent reports[5,6] of work in this field prompt us to describe our experiences.

Holland[3] has described an evaporation source for general use in which reaction between the evaporant and the support material may be avoided by directly bombarding the end of a wire fed into an electron beam. We have used this method for evaporating titanium and found that a molten globule may be easily formed on the end of a wire fed downward, but that it is difficult to attain the high temperature required for rapid evaporation because the globule is taken out of the region of intense electron bombardment by melting back along the wire. Thus either rapid feeding of the wire or increase in the electron intensity only results in the enlargement of the metal globule up to a critical diameter while its temperature remains constant at the melting point (about 1,660° C.). Using a feed wire 1 mm. in diameter, molten titanium droplets can be supported up to a maximum diameter of 5 mm., which give an evaporation rate of 15 mgm./min. at 1,660° C.

We have observed[4] that a globule of titanium may be raised to a very high temperature if the wire is fed downwards through a water-cooled copper block into the electron beam and the metal is allowed to melt back and contact the cooled block. A hemispherical globule is then formed which hangs from a frozen zone adhering to the cooled surface. Should the globule become detached from the feed wire, it remains suspended from the cooled block, and the size of the droplet is limited only by the area of the cooled zone. Thus we have supported titanium hemispheres up to 5 mm. in radius on a block 1 cm. in diameter, while the tip of the molten droplet was raised to a temperature of about 2,000° C.

We have found that it is difficult to cool the feed wire in the guide nozzle, and the exit of a tubular nozzle may become blocked by the titanium melting back and freezing in the tube. To avoid this we have fed the wire down an inclined plane so that it is located at the edge of the anode block without being laterally restricted (Fig. 1). If the wire feed is obstructed when the metal globule sticks to the anode then the wire may bend sideways and continue to enter the beam, in which case more than one globule may be formed. The life-time of the vapour source is solely dependent on that of the cathode filament which is eroded by ion bombardment.

Using such a vapour source inside a water-cooled vessel 18 in. in diameter and feeding wire 40/1,000 in.

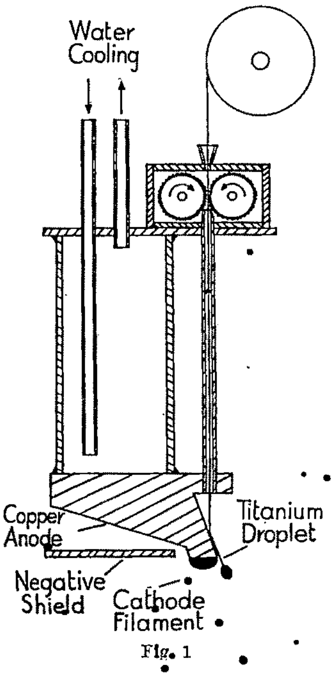

Fig. 1

in diameter we have achieved evaporation rates of up to 250 mgm./min. at a power input of 1·25 kV. and 4 amp. Evaporating at a rate of 100 mgm./min. at 1 kV. and 1·2 amp, we have achieved pumping speeds for air of some 1,000 l./sec. at 10^{-5} mm. mercury. A pump similar to that described was shown at the Physical Society Exhibition in 1958.

Recently, Milleron[5] has described a titanium vapour source in which a molten bead is formed on the end of a wire fed upwards into an electron beam. In our early experiments we used a similar apparatus and found that the viscosity of the metal was greatly reduced as the evaporation temperature rose above the melting point so that the liquid metal ran backwards under gravity and blocked the entry tube.

Winogradoff[6] has described a titanium vapour source in which wire is fed upwards on to the molten tip of a molybdenum rod which is heated by electron bombardment. We have found that it is very difficult to transfer metal to a heated surface in this way because either the feed tube obstructs the emitted vapour or the feed wire melts backwards when traversing the electron-bombardment zone.

If the thermionic cathode of the vapour source bombarded with electrons is grounded, the metal condensing wall of the getter pump may operate as a cold cathode for a glow discharge at pressures above 10^{-4} mm. mercury. Positive-ion bombardment removes absorbed gas from the condensed metal and reduces the electron-bombardment current flowing to the evaporant. We have avoided this by using a cathode heater transformer which is insulated from earth potential at high gas pressures. We have also found that with the condensing wall at a positive potential the pump may be degassed by electron bombardment using an auxiliary cathode[4]. A typical operating cycle of our pump is as follows: the pump chamber is first degassed by electron bombardment and, after the pressure has been reduced to 5×10^{-4} mm. mercury, using a two-stage rotary pump, evaporation is commenced. When the pressure has fallen, due to gettering to 10^{-5} mm. mercury, the cathode is grounded so that the positive ions formed by electrons colliding with gas molecules may be transported to the chamber walls. The combined action of the 'evapor-ion' pump using titanium with a hydrogen content of 0·008 per cent by weight gives an ultimate of 10^{-6} mm. mercury.

Our thanks are due to Mr. R. L. Simpkins for his valued help during the construction of the titanium pump and to Mr. A. S. D. Barrett, technical director of Edwards High Vacuum, Ltd., for permission to publish this communication.

THREE VARIETIES OF HUMAN HÆMOGLOBIN *D*

By S. BENZER* and DR. V. M. INGRAM

Medical Research Council Unit for Molecular Biology, Cavendish Laboratory, Cambridge

AND

DR. H. LEHMANN

St. Bartholomew's Hospital, London

THE list of variants of human hæmoglobin is already an imposing one. Twenty-two are listed in a recent publication[1], many of which have been shown to be genetically determined. Since the identification of hæmoglobin types is ordinarily based upon properties such as electrophoretic mobility, solubility, and chromatographic behaviour on ion-exchange columns it might be expected that the application of more sensitive methods would reveal an even greater multiplicity of forms. Our results with three different hæmoglobin *D* samples confirm this.

Hæmoglobin *D* was discovered by Itano in 1951[2] in an American 'white' family. It has the same electrophoretic mobility[2,3] as hæmoglobin *S* and behaves similarly during ion-exchange chromatography[4]. The two hæmoglobins differ, however, in the solubility of the reduced form[2,3,5]. Only hæmoglobin *S* possesses the low solubility of the reduced form which causes sickling of the erythrocytes.

Hæmoglobin *D* has also been found in an English family with Austrian and Spanish connexions[6] and in a Mulatto family in Britain[7] where it could be traced to the non-Negro mother. There have been records of its occurrence in Algerian Muslims[8], and 35 instances have by now been seen among 5,610 Muslims of mixed origin examined in Algiers (Cabannes, R., personal communication). Studies from Missouri and North Carolina showed an incidence of 0·4 per cent in American Negroes[9]. Large-scale surveys in Africa south of the Sahara have failed to discover hæmoglobin *D* in that area, with one exception where, however, the electrophoretic mobility at alkaline *p*H of the hæmoglobin *D* described[10] was slightly faster than that of *S*. In Asia, one example was discovered in a Persian family[11], and one family with hæmoglobin *D* was found in the course of a survey of 400 unrelated Turks[12]. We have recently seen hæmoglobin in a Turkish Cypriot family.

In contrast to these sporadic findings, hæmoglobin *D* has been found in two Indian populations—the Sikhs and the Gujeratis—at an incidence of 1·8 and 1·1 per cent, respectively[13,14].

We have examined three samples of hæmoglobin *D* coming respectively from a Turkish Cypriot (α), from a Gujerati Indian (β) and from a Sikh (γ), and have found, in fact, that each carries a chemical change in a different part of the hæmoglobin molecule. In all three instances no sickling of the intact red cells was seen when they were reduced with 2 per cent

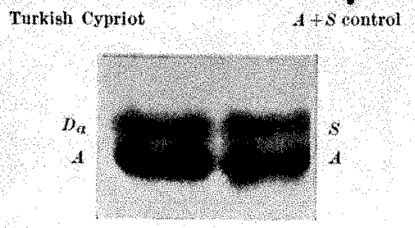

Fig. 1*a*. Comparison by filter paper electrophoresis at alkaline *p*H of the hæmoglobin of the Turkish Cypriot ($A+D_a$) with a hæmoglobin $A+S$ control. D_a and S are indistinguishable by this method

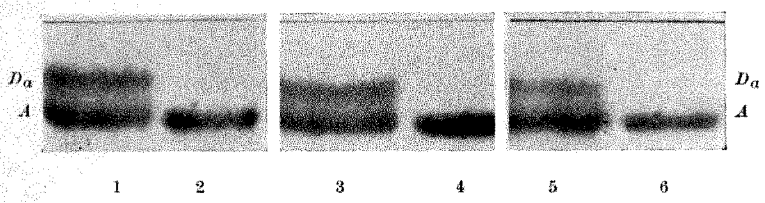

Fig. 1*b*. The hæmoglobins of the family of the Turkish Cypriot (5). Paper electrophoresis at alkaline *p*H. The father and one sister are also hæmoglobin *D* trait carriers. The mother, one sister and one brother possess hæmoglobin *A* only. 1, Father; 2, mother; 3 and 4, sisters; 5, propositus; 6, brother (non-identical twin)

sodium metabisulphite, thus showing that no hæmoglobin *S* was present. On electrophoresis of the purified hæmoglobin solutions, the first two samples resolved into two fractions with the mobilities of hæmoglobin *A* and *S* or *D*, respectively (Figs. 1 and 2), and the third consisted of a single component[15] with the electrophoretic properties of *S* or *D*. Identical results were obtained with ion exchange chromatography (Amberlite *IRC*50). The presence of hæmoglobin *S* could be excluded in all three samples by Itano's solubility test[5], where reduced hæmoglobin *S* and mixtures of reduced hæmoglobins *AS* or *SD* all show a solubility below 5 gm./l. of Itano's 2·24 *M* phosphate buffer at 25°. The ferrohæmoglobins of the Turkish Cypriot (AD_a), the Gujerati (AD_β) and of the Sikh (D_γ) all showed complete and ready solubility at this concentration and temperature.

The specimen from the Sikh (D_γ) could be used without further purification. Hæmoglobins D_a and D_β were isolated from their mixtures with *A* by paper electrophoresis in 0·06 *M* veronal buffer at *p*H 8·6[16]. Each hæmoglobin was denatured by heat and digested with trypsin, as previously described[16,17], to give a mixture of peptides for examination by 'fingerprinting'. The distinction between the three hæmoglobins *D* could be seen readily by one-dimensional electrophoresis[6] as shown in Fig. 3.

In hæmoglobin D_a peptide 23 (see ref. 16) has disappeared, and in hæmoglobin D_β peptide 26 is missing, whereas in D_γ both these peptides are present.

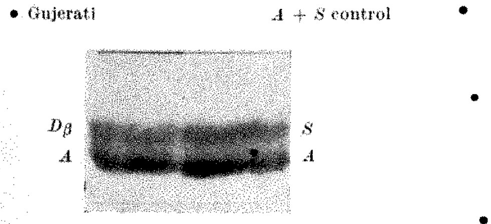

Fig. 2. Comparison by filter paper electrophoresis at alkaline *p*H of the hæmoglobin of the Gujerati ($A+D_\beta$) with a hæmoglobin $A+S$ control. D_β and S are indistinguishable

Further analysis by two-dimensional 'fingerprints' indicated that in hæmoglobins D_a and D_β new peptides had appeared in the band of the neutral peptides, and that in D_γ one of the normal peptides (containing tyrosine) seemed to have disappeared from the neutral band. The exhaustive examination necessary for the precise identification of all changes in amino-acid sequence, as done[16-19] for hæmoglobins *S* and *C*, has not yet been carried out. Enough has been learned, however, to support the conclusion that the three hæmoglobin *D* samples are distinct proteins; also some, if not all, the chemical changes involved have been indicated.

It was particularly surprising that there was a difference between the two hæmoglobins from the two Indians. Though the Gujeratis and the Sikhs represent rather different types of Indian populations, one might have expected that the 1–2 per cent incidence of hæmoglobin *D* would prove a link rather than differentiate between the two. It has been somewhat of a puzzle that surveys of other Indian populations had so far not resulted in the finding of hæmoglobin *D* among them. The present observation that the two hæmoglobins *D* of the Gujerati and the Sikh are the result of distinct mutations would explain the patchy distribution of hæmoglobin *D* in India.

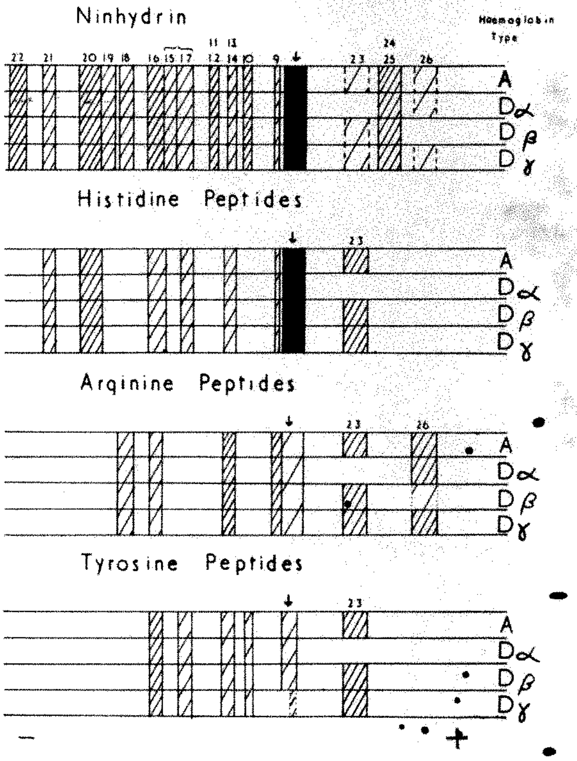

Fig. 3. Comparison by one-dimensional paper electrophoresis[6] of tryptic digests of hæmoglobins A, D_a, D_β, D_γ at *p*H 6·4. Peptides numbers 23 and 26 (see ref. 16) give only weak colours with ninhydrin, even after heating. Both hæmoglobins D_a and D_β by reason of the isolation procedure contain small amounts of hæmoglobin *A*. The colour reaction specific for various amino-acids were carried out as described in ref. 20 under the following authors: ninhydrin—Toennies, 1951; histidine—Karler, 1952, Baldridge, 1953; arginine—Jepson, 1953; tyrosine—Acher, 1952. Arrows indicate neutral points

It is clear that considerable caution will have to be applied to the anthropological interpretation of the distribution of characters such as hæmoglobin D which may be the result of entirely different mutations.

In hæmoglobin S, mutation has been shown to have resulted in the replacement of a negatively charged glutamic acid residue by uncharged valine[16,17]. The similar electrophoretic properties of hæmoglobin D could result from the replacement of any negatively charged amino-acid residue by a neutral one, or from the replacement of any of the many neutral amino-acids of the globin molecule by a positively charged arginine or lysine. In general, however, such altered hæmoglobins might be expected to differ from hæmoglobin S in not having an abnormally low solubility.

In hæmoglobin C the same glutamic acid residue as in hæmoglobin S was found to be affected[19], in that case being changed to lysine. It is important to note, therefore, that mutational alterations are not restricted to that particular location, but may arise, as in hæmoglobins D_α, D_β and D_γ, in various parts of the molecule.

The assistance of Mrs. Rita Fishpool is gratefully acknowledged.

AUTORADIOGRAPHY OF FUNGI THROUGH A LAYER OF SOIL AND IN AGAR CULTURE

By Dr. ERNA GROSSBARD
Grassland Research Institute, Hurley, Berkshire

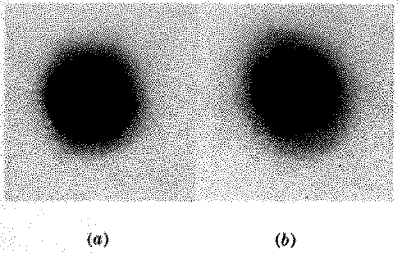
AUTORADIOGRAPHY has become a standard tool of industrial and, to a large extent, of biological research. In the field of mycology it has so far been utilized comparatively little. It is the purpose of this article to describe a few applications of this technique to the study of fungal physiology at the Grassland Research Institute, Hurley.

The subject of autoradiography has been well reviewed by Boyd[1]. He defines it as the "production of a two- or three-dimensional image on a photographic film or plate by radio-active radiation".

In biological research, nuclides emitting β-rays of low energy are most frequently used for autoradiography. We have used β-radiation, but in addition, investigations have been made to exploit by autoradiography the characteristic of deep penetration by γ-photons in order to locate the position of a radio-active fungus inoculum buried in soil. In 1957, Grossbard and Stranks[2] published a preliminary note on their attempt to record the growth of fungi directly in the soil, that is, *in situ*, by labelling the inoculum, locating its position and tracing its growth by means of a scintillation counter. In view of the high energy of γ-photons and consequently poor resolution, because of absorption and back scatter by soil particles, a well-defined and true image of the specimen could not be expected. It was, however, assumed that the possibility of locating a fungal colony in the soil, by so simple a technique as autoradiography, might prove to be a useful research tool even if only a mere shadow could be obtained.

The fungi used in the work described in this paper were: *Armillaria mellea* (Vahl ex Fries) Quél Herb. I.M.I. 61755, *Fusarium culmorum* (W. G. Smith) Sacc. Herb. I.M.I. 35099, *Phycomyces blakesleeanus* Burgeff Herb. I.M.I. 44142, *Phytophthora cactorum* (Leb. and Cohn) Schroet. Herb. I.M.I. 62471, *Rhizoctonia solani* Kühn, kindly supplied by Dr. S. D. Garrett, *Rhizopus stolonifer* (Ehrenb. ex Fr.) Lind. Herb. I.M.I. 42844, and *Verticillium albo-atrum* (Reinke and Berth.) Herb. I.M.I. 62131[1]. The nuclides acting as tracers were the γ-ray emitters caesium-137 and cobalt-60. The fungi were grown in either a nutrient broth or agar, containing the nuclides which they readily absorbed. In broth cultures the mat was harvested and washed with water over a sintered glass filter until the filtrate showed no more activity. In the case of some fungi, especially *P. cactorum*, the tracers continued to be leached out on prolonged washing, but in others a fair proportion of the nuclides was retained permanently in the mycelium. Agar cultures were not washed, and a number of disks or squares served as the inoculum. The mycelium was mixed with a small quantity of soil or sand/oatmeal and buried at various depths in a glass or aluminium dish containing autoclaved soil or placed at the top end of a column of soil contained in a glass tube, that is, a so-called growth tube.

The method of autoradiography used consisted in placing an envelope-packed Ilford X-ray film Industrial *B* beneath and on top of the dish containing soil and the radio-active fungus, or below the growth tube; the film rested on a lead sheet 1/16 in. thick. This lead screen is essential since the photographic effect of γ-photons is, to a large extent, a result of the emission of secondary electrons from lead. Kodak



(a) (b)

Fig. 1. *Armillaria mellea* (cobalt-60). A disk of an agar culture was buried in soil, 1 cm. from the top. Total depth of soil in dish was 5 cm. (*a*) Autoradiogram through lid and 1 cm. of soil, and (*b*) through bottom of dish and 4 cm. of soil. Exposed for 26 days. Note that image in (*b*) is still clearly visible but intensity is much lower and the outlines are blurred

X-ray intensifying screens were tested in a few experiments but no improvement was observed. The preparations were exposed for 14–28 days depending on the activities of the nuclides, the depth of the soil layer and whether an aluminium or glass dish had been used, aluminium absorbing a greater proportion of the radiation than does glass.

Images obtained by this method are depicted in Fig. 1 (*a* and *b*); the experimental conditions are given in the legend.

Whatever the shape of the inoculum, whether it was buried in soil, placed on top of a soil layer or at one end of a soil column, the image in each case was a circular area of blackening, revealing no details of morphology such as the rhizomorphs present in the culture of *A. mellea*. The diameter and the intensity seemed to decrease with an increase in the depth of the soil layer through which the rays had to travel. As is generally the case in autoradiography, concentration of the nuclide and duration of exposure influenced the degree of blackening. Experiments are in progress to establish these correlations on a quantitative basis, taking into account density and moisture content of the soil as well as other factors normally affecting the absorption of radiation. The actual position of the fungus inoculum could be located with some accuracy.

It was possible to obtain an image from inocula containing very low concentrations of the tracer. For example, *V. albo-atrum* was grown in a Dox solution containing caesium-137. The mat, after thorough washing, contained about 3·0 μc. of the tracer. When placed on top of a layer of soil 1½ cm. deep in a Petri-dish the autoradiogram, through the bottom of the dish, produced an image similar to that in Fig. 1*b*. This is an important point, since one of the applications of this method envisaged is the study of the growth of fungi directly in the soil. Even if the original inoculum were to contain a very large concentration of the tracer the outward growth of hyphae would bring about considerable dilution and we might be left with very low activities. A method of autoradiography capable of recording such low activities must be devised. At present two great difficulties will have to be solved before the technique can be used to its full extent for growth studies. First, it has not so far been possible to demonstrate translocation of caesium-137 and cobalt-60 in the soil by the fungi tested by Grossbard and Stranks[2]. On the other hand, there is evidence that, at least in agar cultures, these nuclides were transported in the case of *P. blakesleeanus*, *R. stolonifer* and *P. cactorum*. Second, the long time of exposure necessary to produce an image reduces the value of this method for growth studies. However, as this technique is only in its initial stage of development and is still very crude, it is hoped that ways will be found to reduce the exposure time. Once the technique is perfected it should find various applications especially in plant pathology and, perhaps, also in root-growth studies.

The method described above is primarily based on the effect of gamma-radiation. Both caesium-137 and cobalt-60 emit beta particles in addition to γ-photons. Thus some of the standard techniques of autoradiography which utilize mainly β-radiations could be adapted for our purpose, namely, apposition on a non-screen X-ray film and the stripping film technique as devised by Pelc[3]. Both proved valuable in studies on translocation in fungi[4]. Fig. 2 illustrates an example of apposition on an X-ray film. Fragments of sporangiophores of *R. stolonifer* were removed 2–3 cm. above a substrate containing cobalt-60. The material was teased out in water, allowed to dry on a slide and wrapped in 'Cellophane'. The slide was placed on an Ilford X-ray film Industrial *B*, with the fungus facing the emulsion, wrapped in a lightproof envelope and exposed for 28 days. This long exposure was necessary because of the very small concentration of the tracer, which could barely be detected by a scintillation counter. Exposure could be reduced to 6 days or less in other preparations. As can be seen in Fig. 2 the individual fragments of the sporangiophores and the sporangia are easily discerned. While the tracer had been leached, forming black irregular areas, it is clear that cobalt-60 was translocated through the sporangiophores and accumulated in the sporangia.

The stripping film technique was used for microscopic observations of fungal hyphae. In order to demonstrate absorption and accumulation of a tracer by hyphae submerged in a radioactive substrate, very thin sections of agar cultures of *R. solani* containing cobalt-60 were placed on slides and allowed to dry in order to obtain a thin specimen by dehydration of the agar. The preparations were coated with sections of strippable film (Kodak scientific plate *A.R.*10) as described by Pelc[3], and after exposure for 6–14 days developed in the normal manner. They were photographed unstained under an optical microscope (Fig. 3). The background showed considerable grain

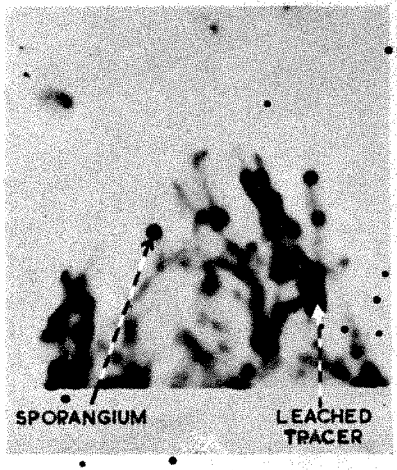


Fig. 2. *Rhizopus stolonifer* (cobalt-60). Autoradiogram of fragments of sporangiophores by apposition on X-ray film. Exposed for 28 days. Note accumulation of tracer in the sporangia. (× 3)

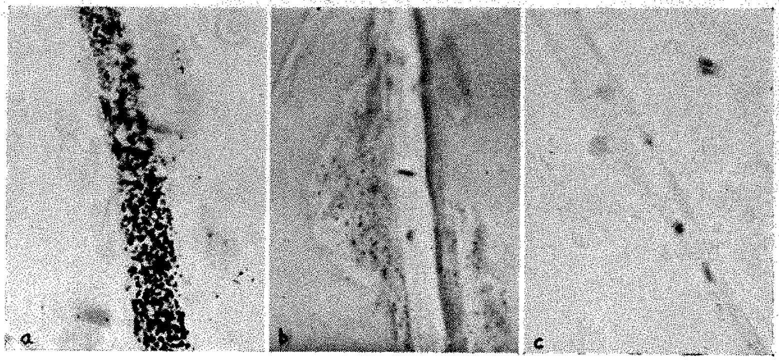

Fig. 4. *Phytophthora cactorum* (cobalt-60). Photomicrograph of autoradiogram of hyphae grown over a coverslip placed on the surface of a substrate containing cobalt-60. (*a*) Hyphal content intact; (*b*) content oozing out; (*c*) empty hypha. Exposed for twelve days. Note the density of grains in (*a*) and their complete absence in (*c*). (×1,340)

density, due to the thin layer of radioactive agar still adhering to the slide. The concentration of grains in the hyphae was considerably greater, suggesting accumulation of the tracer within. In order to study translocation into the aerial mycelium, aerial hyphae of various fungi were removed and teased out in water. An autoradiogram was prepared as before. Here, a considerable difficulty was encountered common in preparation of biological material for autoradiography; namely, leaching of the tracer. Robson (personal communication), who applied Canny's[5] modification of the stripping film technique in her work on the sulphur metabolism of fungi, has overcome this by freeze-drying and embedding the specimen in wax under vacuum. The hyphae were afterwards sectioned. While this method was being studied in our laboratory, attempts were made to prevent leaching of cobalt-60 by converting it into the insoluble sulphide. After the culture had been made alkaline a gentle stream of hydrogen sulphide was bubbled through. However, although the tracer was precipitated, there were so many side-effects and artefacts that interpretation became difficult. A useful method was devised by Barton (personal communication). The radioactive agar was inoculated with the fungus under study and then coverslips 38 × 22 mm. were placed so as to just touch the surface of the agar. On incubation some fungi such as *P. cactorum*, *R. solani* and *F. culmorum* grew over the cover slips forming a thin mat, sometimes of only a few hyphae. This made an ideal preparation for the stripping film technique, which requires a thin specimen. The need for teasing out was dispensed with. By careful removing of the coverslip a minimum disturbance of the hyphae was achieved. The coverslips were cemented to an ordinary microscope slide and autoradiograms prepared. We have found that the rapid immersion into a water-bath in order to lift up the sections of strippable film, if followed by rapid drying in a tower (designed for this purpose at Hurley by Barton), did not give rise to any appreciable leaching of the tracer. Fig. 4 (*a* and *c*) shows autoradiograms prepared by this method from a sand/oatmeal culture of *P. cactorum* containing cobalt-60 of very low activity. The preparations were photographed unstained under a phase-contrast microscope. Fig. 4*a* depicts a hyphal section with its content intact and a considerable density of silver grains as a result of the concentration of the tracer; in 4*b* the hyphal content seems to have oozed out through a rupture in the cell wall, apparently carrying with it the tracer; in (*c*) we see an empty hypha, that is, the mere cell wall and no silver grains at all. These observations would suggest that cobalt-60 is transported by protoplasmic flow rather than held by the cell wall. Though further indications supporting this hypothesis have been obtained with, for example, *P. blakesleeanus* by Grossbard and Stranks[4] a great deal more experimental work is required for confirmation of a conclusion of such fundamental importance. These experiments, however, illustrate the potentialities of the stripping film technique and autoradiography in general in fungal physiology. Another interesting application, of the stripping film technique, was reported recently by Staples and Ledbetter[6] in their studies on the distribution of tritium-labelled glycine in rust-infected leaves.

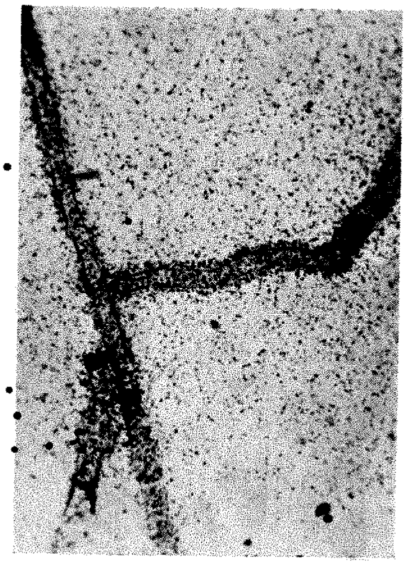

Fig. 3. *Rhizoctonia solani* (cobalt-60). Photomicrograph of autoradiogram of mycelium submerged in agar containing cobalt-60. Note larger grain density within hyphæ. Exposed for 14 days. (×340)

This article outlines but a few applications of autoradiography. Other methods described in the literature may be adapted as useful tools for the study of mycology and plant pathology.

My sincerest thanks are due to Dr. William Davies for his interest in this work, for the encouragement and guidance he gave me and for providing me with facilities to carry on these studies, and also to Mr. G. E. Barton for his valuable collaboration and technical assistance.

HANDBOOK OF RESPIRATION

Prepared under the direction of the Committee on the Handbook of Biological Data, Division of Biology and Agriculture, National Academy of Sciences, National Research Council of America. Analysed and compiled by PHILIP L. ALTMAN, JOHN F. GIBSON, M.D., and CHARLES C. WANG. 403 pages. 52s. 6d.

This new book is a compilation of all known useful quantitative data pertaining to the mechanisms of gas exchange in man and laboratory animals. It represents the contributions of some 400 outstanding authorities in the field. Most of the information is presented in handy tabular or nomographic form.

Symposium on Latency and Masking in Viral and Rickettsial Infections

Editors: DR. DUARD L. WALKER, DR. ROBERT P. HANSON and DR. ALFRED S. EVANS, *University of Wisconsin.*

A record of the proceedings of a symposium held at the University of Wisconsin in September, 1957, this volume represents the results of an international meeting of eminent authorities to consider problems in latent infections. It contains discussions and exchange of information of workers from the United States, Canada and Europe, representing the major subdivisions of virology—plant, insect, bacterial and animal—and includes several experts on tumour viruses.

An *outstanding contribution* of the conference was the effort to clarify and modify terminology to fit the current state of information relevant to latent infections

An Introduction to Scale Co-Ordinate Physics

WILLIAM BENDER, *Head of the Department of Physics, University of South Dakota*

This book develops a new approach to quantum theory in physics. Dr. Bender develops a set of macro operational concepts in terms of which a macro operational programme is outlined. This programme is carried forward to the emergence of a scale co-ordinate geometry in terms of which certain familiar quantum concepts in physics receive a natural macro representation (based on gross apparatus performance). A new type of analytic geometry, 'scale co-ordinate geometry,' emerges from a consideration of the operations on, and configurations of, gross apparatus. Many diagrams of well-known pieces of (gross) apparatus are included.

THE WORLD'S GREATEST BOOKSHOP

FOYLES
✦ FOR BOOKS ✦

Any morning's post at Foyles includes an extraordinary variety of requests. From Nicosia, for instance, comes an order for a book on watercress cultivation; a trio of television singing sisters asks for three copies of 'War and Peace'; and a much-married American entertainer enquires (a trifle wearily, we thought) about Dr. David Mace's 'Marriage: The Art of Lasting Happiness.' Book-buyers throughout the world send to Foyles for all their book requirements.*

* *We were able to supply all three books from stock.*

MACMILLAN BOOKS

Mountains in the Sea

MARTIN HOLDGATE

The superb story of the Gough Island Expedition, with a foreword by H.R.H. Prince Philip, Duke of Edinburgh. A book of new discoveries, excitements and fascinating anecdotes of birds and animals, seen in surroundings of great natural beauty.
6 pages of magnificent colour photographs and 32 pages of halftones 25*s*

Solid State Physical Electronics

PROFESSOR ALBERT VAN DER ZIEL

A comprehensive introduction to the physics of the solid state devices that are used, or are being developed for use, in the electronics industry. *Illustrated* 37*s* 6*d*

Atlas of the Sky

VINCENT DE CALLATAŸ

A unique atlas, containing 72 pages of text and 36 plates, for the use of amateurs of astronomy. Translated and with a Foreword by Sir Harold Spencer Jones, former Astronomer Royal. 'The whole work is simply and most admirably planned.'—*Sphere*. 'It is just what the amateur astronomer wants.'—*Financial Times*. 65*s*

The Man-made Fibres Industry

R. ROBSON

AUTHOR OF *The Cotton Industry in Britain*

The first book to tell of the development and structure of the industry, its economic and scientific basis, in England and overseas. 'Compactly written . . . to the point and right up-to-date. It can be thoroughly recommended to anyone who is confused by the complexity of the situation within the man-made fibre industry in which new fibres are emerging daily.'—*Skinner's Silk and Rayon Record*. 21*s*

EVOLUTION OF GENETIC SYSTEMS

C. D. Darlington

Genetics is here presented as the study of systems of heredity and variation, systems which rest on a basis of the chromosomes and are related to one another by processes of natural selection. The book also shows that the chromosome theory is now something more than a profession of faith or even an instrument of genetic discovery : it is the key with which we are opening the door between the physical and biological sciences.

264 pages. 21s. net.

GENETICS IN THE ATOMIC AGE

C. Auerbach

A study dealing with a subject which is of vital interest to us all. To appreciate the widespread concern among doctors and scientists it is necessary to understand the genetical principles of heredity and mutation. Dr. Auerbach, one of the world's foremost pioneers in these fields, helps us to that understanding, and her exposition is aided by a large number of illustrations.

114 pages. 8s. 6d. net.

THE ORIGIN OF LIFE ON THE EARTH

A. I. Oparin

During the 1920's Professor Oparin's book on the origin of life aroused great interest in scientific circles. Since then, many new discoveries have been made which have tended to confirm the theories of Oparin. This book is a completely re-written account of those theories along with discussion of all the relevant scientific material which has come to hand since that time.

First Quality

STOP WATCHES

for Scientific use

This 603 stop watch is ideal for research. It combines a fast escapement 1/10th. second with a split facility and a 30 minute recorder. It is also accumulative — enabling successive observation to be totalized. It is usually supplied complete with N.P.L. Certificate.

Repair service. Our skilled repair staff deals with all types of watches, clocks and associated equipment. "Crash" service—ring MUSeum 2255.

Sectional catalogues and leaflets available

Watches, stop watches and chronographs. Clocks: aircraft, domestic, industrial, architectural and turret. Revolution counters, tachographs and associated equipment. Process timers and time interval meters. Electronic instruments. Marine chronometers, electrically controlled stop watches and kymographs.

NEW ACADEMIC PRESS BOOKS

RUSSIAN-ENGLISH MEDICAL DICTIONARY

By Stanley Jablonski, *National Library of Medicine, Washington, D.C.*
Edited by B. S. Levine, *formerly National Institutes of Health, Bethesda, Maryland.*
November 1958, 423 pp., illus., approx. 88s.

The purpose of this dictionary is to provide a specialized tool for the translation of Russian medical literature into English.

All principal branches of medicine and all main paramedical sciences such as histology, pathology, dentistry, veterinary medicine, are represented in this work. Particular attention is given to areas in which misunderstandings of nomenclature may result from the difference in approach followed by Russian and English-speaking medical scientists. A wide variety of names of plants used in medicine as well as those of potential interest to medical scientists is included.

The dictionary contains an extensive number of Pavlovian terms which are usually accompanied by complete definitions. Modern Russian drugs are listed with American equivalents, synonyms, and pharmacological data.

This work will prove especially useful to Western researchers because it provides broad coverage of areas peculiar to Russian medicine and contains complete definitions where common English equivalents are not available.

CHOLESTEROL

Chemistry, Biochemistry, and Pathology

Edited by Robert P. Cook, *University of St. Andrews, Queen's College, Dundee, Scotland.*
May 1958, 542 pp., illus., 107s. 6d.

CONTENTS:

Henrik Dam, Historical Introduction. Peter Bladon, Chemistry. Robert P. Cook and James B. M. Rattray, Methods of Isolation and Estimation of Sterols. Robert P. Cook, Distribution of Sterols in Organisms and in Tissues. George S. Boyd and Michael F. Oliver, The Physiology of the Circulating Cholesterol and Lipoproteins. R. Gordon Gould, Biosynthesis of Cholesterol. R. Gordon Gould and Robert P. Cook, The Metabolism of Cholesterol and Other Sterols in the Animal Organism. Oscar Hechter, Conversion of Cholesterol to Steroid Hormones. Geoffrey H. Bourne, Microscopical Localization of Cholesterol in Cells and Tissues. David Adlersberg and Harry Sobotka, Pathological Manifestations of Abnormal Cholesterol Metabolism. Irvine H. Page, Treatment of Disorders of Cholesterol Metabolism. Werner Bergmann, Evolutionary Aspects of the Sterols. Marjorie G. Horning, The Sterol Requirements of Insects and of Protozoa. Thressa C. Stadtman, The Microbial Metabolism of Steroids. Robert P. Cook, Some Relations of Cholesterol to Other Lipids. Appendix of Practical Methods. Author Index—Subject Index.

WHATMAN

Glass

Fibre

Papers

- **excellent retention with rapid filtration**
- **high softening point**
- **outstanding chemical resistance**

These brilliant white, exceptionally strong papers are composed entirely of glass micro fibres with no added binding materials. Their excellent retention properties make them particularly useful for filtering very fine precipitates and semi-colloidal substances through a coarse porosity crucible. The filtration rate is very rapid, and there is no risk of blocking.

The papers are also recommended for routine filtration through Buchner and Hirsch funnels, and for certain applications in Chromatography and Electrophoresis. Although in the latter techniques they do not replace conventional Whatman papers, the intrinsic properties of Glass Fibre Papers can be utilised effectively for investigating non-aqueous systems, organic mixtures of protein origin and several other substances.

Please write for technical literature.

SUNVIC

PULSE HEIGHT ANALYSER

Instruction in use and maintenance of the Sunvic P.H.A., and in analysis techniques is available. Details on request

Pulse height analysis methods are invaluable in the investigation of problems in nuclear physics and radiation spectroscopy. The Sunvic P.H.A. is particularly suited to such applications and is available on short delivery. It will accept a random sample of up to 1250 pulses per second and sort them into groups of known height. A magnetostrictive delay line storage system is used, the memory capacity being 100 channels of more than 16,000 pulses each or 70 channels of more than 10^6 pulses each: the illustration shows a typical 70-channel display pattern.

Application Leaflet 21 describes use of the P.H.A. in nuclear spectroscopy. Technical Publication [illegible]131 gives specification, dimensions, etc., for the instrument. Copies of both will gladly be sent on request to:

COMPOUNDS OF THE PRECIOUS METALS
RARE EARTHS
COMPOUNDS OF MINOR AND RARER METALS

CHEMICAL PRODUCTS

From the earliest days of the company, the compounds of silver, gold and the platinum metals have been among Johnson Matthey products. More recently, the experience and manufacturing resources built up over the years have been turned to the preparation of other important compounds, and there is available to-day a wide range of specialized inorganic chemicals of high purity—the simple and complex salts of the precious metals, compounds of minor and rarer metals, and rare earths.

Publication 1750, free on request, gives details of the chemical products in regular supply.

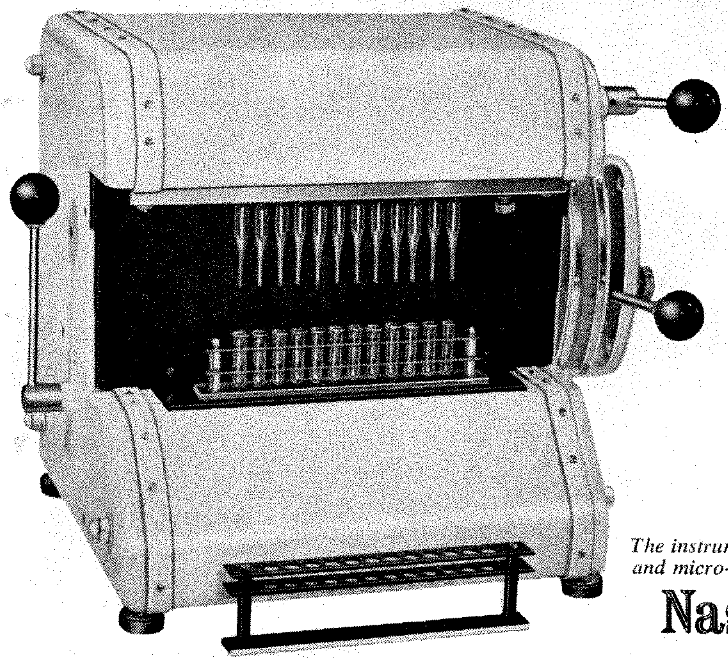
. . . A NEW INSTRUMENT BY NASH AND THOMPSON

THE SEROLOGICAL DISPENSER



This automatic dispenser for multiple titrations was developed at the Lister Institute of Preventive Medicine for routine serological investigations. The apparatus allows the performance of up to 12 titrations in a single operation with even less manipulation than required for a single test by conventional technique.

- *** Volume range 0.01 ml to 1.0 ml.**
- *** Automatic loading of up to 12 pipettes.**
- *** Simultaneous dispensing from all pipettes.**
- *** Accuracy better than that obtainable using Grade 'B' British Standard serological volumetric glassware.**

The instrument has possible applications in micro-chemistry and micro-biology. For further information write to:

HEATING TAPES

for easily controlled temperatures up to 450° C., 600° C. and 800° C.

Five basic designs have been developed by Electrothermal, the originators of heating tapes, all of which afford easy application and economical operation. They are available from all Laboratory Supply Houses in a large variety of widths and lengths.

Other forms of surface heaters are available for :

- Temperatures up to 1,000° C.
- Frost protection
- Flameproof areas
- Damp conditions

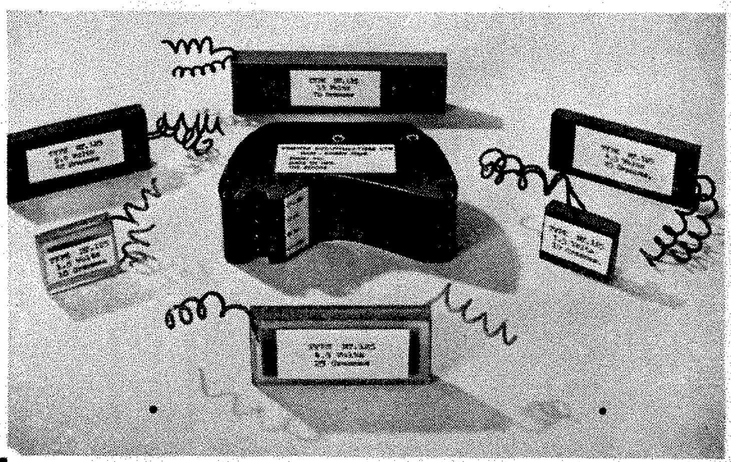
Your Power Problem CAN be solved!

with the HT125 Resin Sealed Silver-Zinc Accumulator

This new Type HT125 Cell and Battery has been produced to meet the needs for small, light, rechargeable batteries of any desired voltage, and capable of supplying power in a limitless range of applications.

The design is based upon the production of strips of 1 to 10 cells which can be arranged in any desired form. The result is a battery which is hermetically sealed, requires no topping-up or maintenance, and will fit into any odd space which so often is all that is available for power supply. Write for full technical details and brochure N



The HT125 cell has a nominal capacity of 0.125 ampere hours, and is suitable for discharge from 10 to 500 milliamps. A single cell weighs $\frac{1}{3}$ oz., measures $1\frac{1}{3}$ in. × $1\frac{1}{4}$ in. × 9/32 in.

Have you realised the potentialities of near Infra-Red Analysis under high resolution?

For analysis and control, High Resolution has opened up a whole new field in the use of the near infra-red.

A high percentage of analyses previously thought possible only in the rock salt region are now being carried out on Mervyn Instruments.

Quantitative and qualitative analyses of many hydrocarbons are easily undertaken, chlorinated compounds of many types can be identified. Methods are available for the examination of complex phthalates. Heavy water analysis can best be carried out in the near infra-red.

Please write to Dept. IS/4 for the specification of the latest Mervyn N.P.L. INFRA-RED SPECTROMETER, together with additional data on analysis in the near infra-red, under high resolution.

PUPIL UNREST: AN EXAMPLE OF NOISE IN A BIOLOGICAL SERVOMECHANISM

By LAWRENCE STARK
Section of Neurology, Yale University

FERGUS W. CAMPBELL
Physiological Laboratory, University of Cambridge

AND

JOHN ATWOOD
Perkin-Elmer Corporation, Norwalk, Connecticut

THE pupil of the human eye continuously undergoes small fluctuations in area even in steady illumination. These movements may be readily seen on close inspection. We considered it worth-while to investigate this pupil unrest as an example of noise in a biological system. We have therefore measured and described the phenomenon, performed experiments to decide between possible mechanisms for its production, and finally considered its possible function.

Description of the pupil unrest. One-minute samples of pupil area fluctuations were recorded. The power spectrum of a typical record is shown in Fig. 1. The power spectra are unreliable below 0·05 c./s. due to the short length of the time functions, and above 2 c./s. because the sampling rate limits the significance of the data. The autocorrelation function and the power spectra both show that the major component of the pupil unrest is random noise in the frequency-range 0·05–0·3 c./s. In the region 0·75–2·5 c./s. all three power spectra we have obtained show a general slope of 36 decibels per octave, with a corner frequency near 0·5 c./s. One power spectrum obtained from a time function of pupil diameter fluctuations showed the same corner frequency and an 18 decibel per octave slope. Power spectra of diameter fluctuation should have half the slope of area fluctuation.

The power spectra in the frequency-range 0·5–2 c./s. show an irregular distribution of power with frequency, which can be seen in the log–log plot of Fig. 1. Both the time functions and the autocorrelation functions have features which suggest the existence of coherent signals at approximately 2 c./s. However, study of the amplitude of these features in the autocorrelation functions and the power spectra show that if such signals exist they represent less than 5 per cent of the root-mean-square value of the time function.

The origin of pupil unrest. It is possible to make some deductions about the origin of the pupil unrest from information already known about the pupil light reflex, from the new results presented, and from the results of certain critical experiments described below.

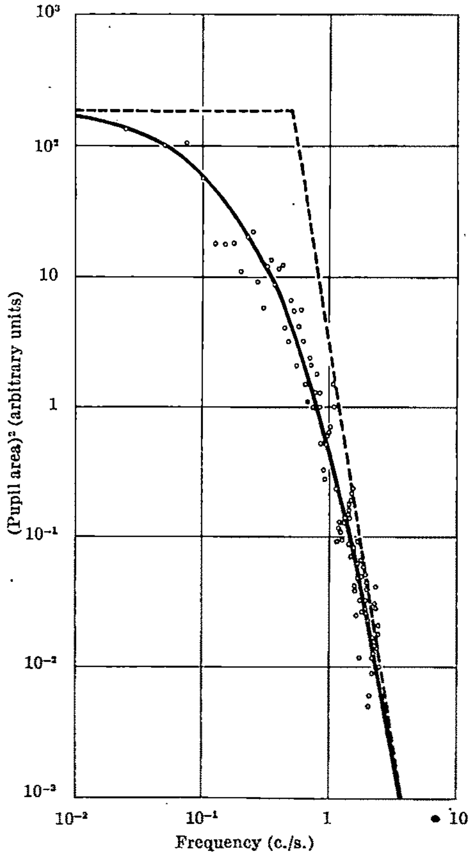

Fig. 1. Power spectrum computed from autocorrelation function of experiment No. 5. Broken lines indicate approximate asymptotes. Area squared in arbitrary units

The unrest cannot be a manifestation of instability in the pupil light reflex considered as an error-actuated servomechanism[1]. Such systems may oscillate, if the feed-back path which completes the loop carries a response delayed by time lags and sufficiently amplified to produce regenerative action[2,3]. Considerable lags exist in the pupil system, but the necessary amplification is not present as the gain is equal[4] to 0·16. The transfer function $G(s)$ is $\{0\cdot16 \exp(-0\cdot18s)\}/(1 + 0\cdot1s)^3$. Thus the pupil will not continue to respond to a stimulus that does not itself continue, and the pupil light reflex servo-loop is therefore stable. The absence of a large coherent frequency component at the frequency that such instability oscillations would be expected[1–4] is additional evidence against this possibility. Furthermore, as no regenerative instability is possible when the loop is open, pupil unrest should continue and appear unchanged under open-loop conditions. This is found to be true experimentally[5]. Thus, quite independently of the quantitative arguments above, we can discard the hypothesis that an unstable pupil loop produces the pupil unrest.

Other non-linear properties of servo-systems such as backlash or dead space also cause oscillations. However, the pupil loop does not show the change in gain with amplitude which would be found if substantial amounts of backlash or dead space were present[6]. Again, these non-linearities require closed loop operation in order to produce oscillations.

The above discussion eliminates causes of unrest associated with the closed-loop properties of the light reflex. Therefore, the unrest must originate in or be injected into the loop. Another observation suggests that this point of origin or injection must be into that portion of the loop which is common to both iris muscles. Only central nervous system elements, including the retina, comprise this portion of the loop. Fig. 2 shows the unrest of one iris to be highly correlated with the simultaneously recorded unrest of the contralateral iris. This excludes an otherwise likely source of pupil unrest—spontaneous movements of the iris muscle—of the type seen in a wide variety of smooth muscle when isolated and free from nervous influence.

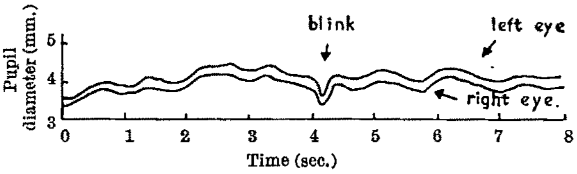

Fig. 2. Record of pupil unrest from right and left eye simultaneously, showing the high degree of correlation

The distinction between origin within and injection into the pupil reflex system can be made by comparing the frequency response of the open loop system with the power spectrum of the unrest. In Fig. 3 are plotted approximate asymptotes for (*A*) the pupil servo-system and (*B*) a lumped parameter network which would attenuate white noise to produce a power spectrum similar to Fig. 1. It is evident that the frequency distribution of the power spectrum of the pupil unrest cannot have been caused by a filtering action of either the open-loop or closed-loop pupil system on noise with uniform distribution of power with frequency. Furthermore, the filter which has shaped the power spectrum of this noise cannot be in series with the flow of information in the pupil system loop, because the measured frequency response of the pupil system does not have the 18 decibel per octave asymptote from 0·5 to 1·0 c./s.

It must be clearly understood that this band-width argument implies nothing about the actual anatomical location of the noise generator. For example, the noise may be leakage from signals external to the pupil system (cross-talk) or it may arise from part of the neurological apparatus which comprises the pupil system, as, for example, the retina. In such cases, although the noise generator and the pupil loop are anatomically united it must still be true that they are functionally and physiologically separate; that transmission of light information relevant to the operation of the pupil system cannot pass in series through the noise generator filter.

However, other experiments could localize the noise generator. For example, careful quantitative comparison under open-loop and closed-loop operating conditions could determine whether the noise is injected at the loop input or elsewhere. Because of the low loop gain and the low magnitude of the fluctuations (± 10 per cent change in area) this experiment is technically difficult and has not been satisfactorily performed. To identify the input which injects noise into the pupil system it is necessary to establish some measure of cross-correlation between the presumptive input and the pupil unrest.

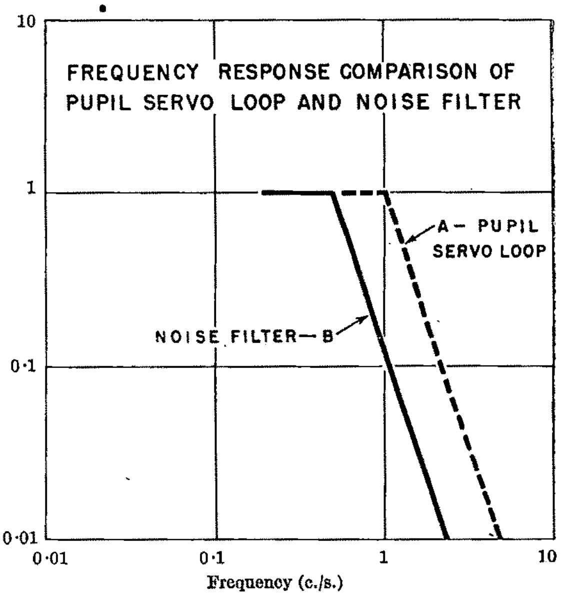

Fig. 3. Approximate asymptotes for (*A*) pupil servo-system and (*B*) lumped parameter network which would attenuate white noise to produce a power spectrum similar to Fig. 1. Both are normalized to unity gain in mid-frequency range

The role of pupil unrest. Pupil unrest might play a specific part in the visual process, or it might represent the tolerance of the pupil servomechanism to uncorrected error. It is unlikely that pupil unrest prevents the disappearance of a stabilized image[7] or produces information of value to the accommodation mechanism as use of a fixed artificial pupil does not affect the characteristics of these functions. On the other hand, since visual acuity is not appreciably influenced by a ± 15 per cent change in pupil area, it seems reasonable that pupil area need not be controlled within more precise limits. Perhaps this is an example of economy in construction in the sense that unnecessary requirements are not placed on the noise level in the pupil apparatus.

We wish to thank Prof. P. Schultheiss for helpful discussion; H. Kunz (Perkin-Elmer Corporation), Dr. G. Dahlquist and Dr. Bergstrand (Swedish Computing Board and the Yale Computing Laboratory) for carrying out the computations; Dr. Irene Lowenfield and Prof. O. Lowenstein for allowing us to conduct an experiment in their Pupillography Laboratory at Columbia University and for helpful discussion; the W. E. Durham Fund, National Institute of Neurological Diseases and Blindness, the National Science Foundation, and the W. H. Ross Fund for support for portions of this work.

Comparison of an Ammonia Maser with a Cæsium Atomic Frequency Standard

Several atomic frequency standards of different types are now in use for comparisons with astronomically determined time. As the adopted frequencies of these atomic standards have been derived from the smoothed universal time U.T.$_2$, which is itself variable in time[1], they disagree by several parts in 10^9. In order to obtain a uniform base for the atomic times determined by the different standards, their frequencies have to be compared directly. This has been done between cæsium resonators at the National Physical Laboratory in Teddington and the Naval Observatory in Washington using the *GBR* 19·6 kc./s. transmissions. Later the same comparison was repeated between similar cæsium resonators at the National Physical Laboratory[2].

The present communication reports on similar measurements between the cæsium resonator of the National Physical Laboratory and the ammonia maser in operation at Neuchâtel. Such a comparison is of particular interest to prove the consistency of atomic and molecular frequencies produced by completely different devices.

Two different methods of reception were used.

(1) The phase of the time signals superimposed on the *MSF* 10 or 5 Mc./s. standard frequency transmissions received in Neuchâtel was differentiated over six days centred on the days when the quartz clocks were calibrated in terms of the maser frequency standard. An accuracy of approximately ± 1 part in 10^9 is achieved.

(2) The frequency of the *MSF* 60 kc./s. standard frequency transmission is connected to the maser frequency obtained the same day. The accuracy given by this method seems better, a few parts in 10^{10}, though the reception on 60 kc./s. is often bad. The results obtained by using the corrections published by the National Physical Laboratory which have to be applied to *MSF* to obtain the frequency based on the cæsium resonator are summarized in Table 1. The correction to be applied to the adopted maser frequency (23 870 129 235 c./s.) to reduce it to the adopted cæsium resonator frequency (9 192 631 830 c./s.) is 9×10^{-9}. Within the limits of accuracy, both methods agree. It is not yet clear if the systematically lower values given by method 1 in autumn 1957 are due to relative drift of the atomic standards, statistical error or ionospheric disturbance.

Comparison of Astronomical Time Measurements with Atomic Frequency Standards

Atomic frequency standards have been in regular operation in several laboratories for the past few years. It has rapidly become clear that they can be used for comparisons with astronomical time determinations.

This problem has been studied in Neuchâtel, where the atomic frequency standards (ammonia masers) have been used to define an atomic time in conjunction with a set of quartz clocks. The same clocks are related to the time determined astronomically (U.T. defining the angle of rotation of the Earth) with a photographic zenith tube and a Danjon astrolabe. The precision of these different comparisons is given roughly in Table 1.

Table 1

Type of measurement	Frequency	Ref.	Clock correction	Ref.
Atomic	10^{-10}		$3\,T + 2\sqrt{T}$ m.sec. (T in years)	*a*
Astronomical: universal time (U.T.)	$1{\cdot}6 \times 10^{-9}$	*b*	3 m.sec.	*c*
Ephemeris time (E.T.)	(5×10^{-9})	2	(30 m.sec.)	2

(*a*) Obtained by integration of the frequency of a quartz clock calibrated every two weeks in terms of atomic frequency.
(*b*) Obtained from astronomical data over a period short enough (about 1 month) to allow differentiation (ref. 1).
(*c*) Average over 1–2 weeks, the accuracy being partly limited by the uncertainty of polar motion.

It appears that atomic and astronomical clock corrections can be compared with similar accuracies whereas astronomical frequencies are much less precise. This follows from the fact that integration of atomic frequency by a quartz clock can easily be achieved without loss of relative accuracy, while astronomical data do not lend themselves to precise differentiation.

On the other hand, it seems preferable, for studying the rotation of the Earth, to use the U.T.$_1$, in which polar motion has been removed and which is a direct result of observation and therefore identical for all observatories.

If one assumes that atomic time (A.T.) is uniform, U.T.$_1$ – A.T. is a direct measure of all effects changing the rotation of the Earth. This quantity, as determined by different observatories and atomic frequency standards, should be directly comparable except for a linear term originating from the adopted atomic frequency. Fig. 1 shows such a comparison. Even small and rapid changes in the rate of rotation of the Earth can be detected, whereas these disappear in Fig. 2, where the differentiated astronomical data are plotted against atomic frequency. Besides the

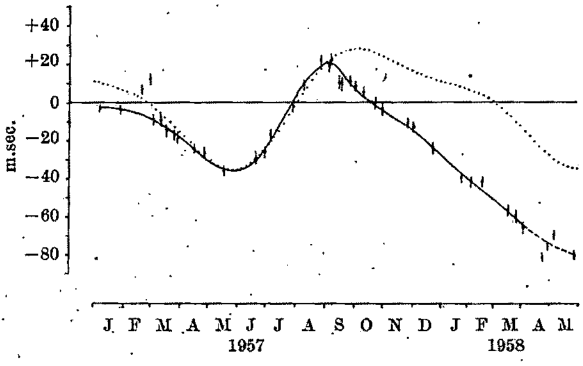

Fig. 1. Universal time (U.T.$_2$) plotted against atomic time. Points represent about 100 stars observed with the PZT. The dotted line is the predicted seasonal variation in the rotation of the Earth (T_s)

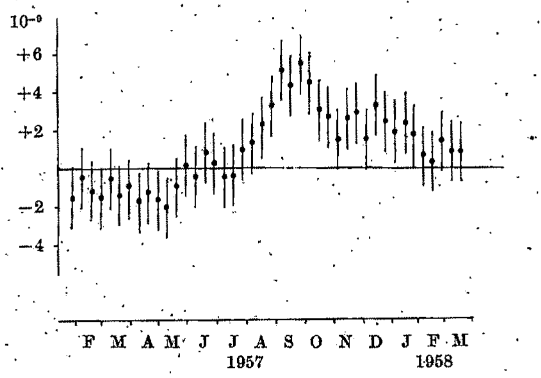

Fig. 2. Corrections to be applied to the adopted frequency of the Neuchâtel maser (23 870 129 235 *Hz*) to obtain frequency U.T.$_2$

accidental scatter of the points the gradual slowing down of the Earth of about 4×10^{-9} a year found in 1957 is in agreement with the measurements of Essen *et al.*[3]. The points in 1958 seem to indicate that this change in speed of rotation may not continue at the constant rate observed since July 1955.

Hence it would seem desirable that research centres using atomic frequency standards should also determine an integrated atomic time in order to allow a better comparison with astronomical measurements with regard to the rotation of the Earth.

An Irregularity in the Atmospheric Drag Effects on *Sputniks* 2 and 3 (Satellites 1957β, $1958\delta_1$ and $1958\delta_2$)

THE atmospheric drag acting on an Earth satellite shows itself most clearly by reducing the period of revolution T, and any irregularities in the rate of decrease of T are likely to be caused by irregularities in either the atmospheric density near perigee or the effective drag cross-sectional area S, of the satellite. For an orbit of small eccentricity e, the rate of change of period dT/dt is given by:

$$-\frac{dT}{dt} = \frac{3SC_D\rho_p}{m}\sqrt{\frac{\pi aH}{2e}}\{1 + 0(e)\}$$

where ρ_p is the air density at perigee, H the atmospheric scale height, a the semi-major axis of the orbit, C_D the drag coefficient (usually taken as 2) and m the mass of the satellite. Since the changes in a and e are very slow, it is ρ_p and S, and to a lesser extent H, which are likely to be responsible for irregularities in dT/dt.

Table 1. COMPARISON OF ORBITAL ELEMENTS FOR *Sputniks* 2 AND 3

Date Satellite	1957 Nov. 3.2 1957β	1958 May 15.3 $1958\delta_1$	 $1958\delta_2$	1958 Jan. 1.0 1957β	1958 Aug. 1.0 $1958\delta_1$	 $1958\delta_2$
Eccentricity, e	0·099	0·110	0·111	0·081	0·094	0·106
Perigee distance (nautical miles)	3,557	3,557	3,557	3,554	3,555	3,556
Perigee latitude	51° N.	50° N.	50° N.	33° N.	29° N.	29° N.
Inclination to equator	65·33°	65·2°	65·2°	65·30°	65·2°	65·2°

Perigee distance is from the centre of the Earth. 1 nautical mile, 6,080 ft.

In providing the prediction service for *Sputniks* 2 and 3, it has been necessary to keep day-to-day records of T, the value of which is usually obtained[1] correct to 1 part in 20,000. Fig. 1 shows the variation of T with time for each of the satellites during the first three months after launching, while Table 1 gives values of other relevant orbital elements, at launch and at one later time.

It will be seen that on all three curves in Fig. 1 a marked change in slope occurs when perigee is at

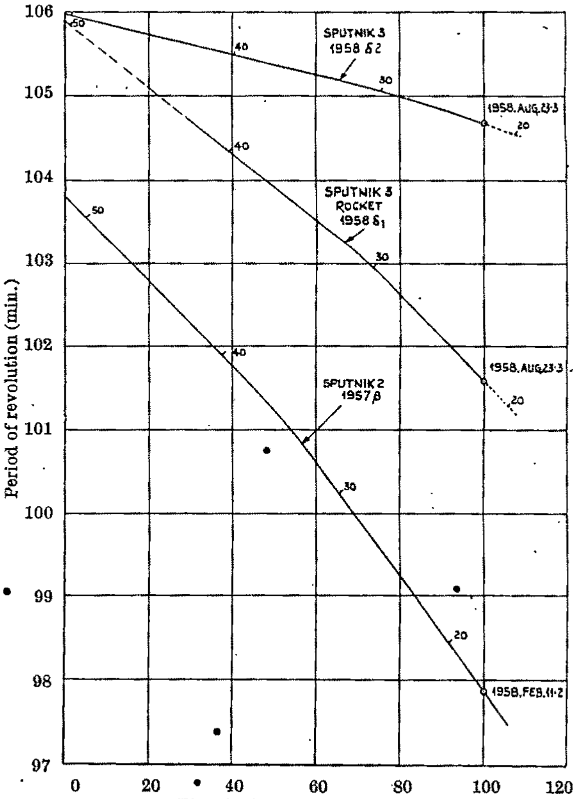

Fig. 1. Variation of period with time for *Sputniks* 2 and 3. Numbers on the curves indicate perigee latitude (deg. north).

Crown copyright reserved

a latitude near 30° N., the value of $-\mathrm{d}T/\mathrm{d}t$ increasing by a factor of 1·35 ± 0·02. Also from Table 1 it appears that the orbits of the three satellites were very similar near the time of the change, and in particular that the perigee heights were almost identical.

When information was available only on *Sputnik* 2, it was not possible to say whether the abrupt change in slope was caused by a change in S or in $\rho_p\sqrt{H}$. But now the same phenomenon has occurred with three satellites of widely differing mass, shape and size, and it is scarcely credible that all three should, when their perigee latitude was near 30° N., have altered their mode of rotation so as to change their effective cross-sectional area by the same factor. The more plausible explanation is that $\rho_p\sqrt{H}$ increases quite sharply when going south near latitude 30° N.; and since H would tend to increase if ρ_p increased, it seems probable that the air density at a height of 120 nautical miles (220 km.) increases considerably somewhere between latitude 35° N. and 28° N.

If this conclusion is correct, a similar change in slope would be expected with the rocket of *Sputnik* 1 $(1957\alpha_1)$. The information available to us on this satellite is not sufficiently accurate to provide a test. Any similar changes in the United States satellites 1958α, 1958β and 1958γ would not be so readily observable because the movement of perigee is much more rapid.

Observation of a Solar Flare at 4·3-mm. Wave-length

During a programme of solar observations at a wave-length of 4·3 mm., scans were made across the Sun on September 25, 26 and 27, 1957. The radio telescope used for these observations has a half-power beam-width of 6·7 minutes of arc. The antenna reflector is an aluminium paraboloid, 10 feet in diameter with a focal length of 35·8 inches. The receiver is mounted on the back of the antenna and is a Dicke-type radiometer consisting of a superheterodyne receiver preceded by a motor-driven attenuator wheel. This radio telescope has been described in a previous publication[1]. The observations were made by pointing the antenna ahead of the Sun and locking it in position. The radiometer output was then recorded continuously as the Earth's rotation carried the Sun's image through the antenna beam. The scans were made across a large plage region located in the eastern part of the solar disk. The scans for each of the three days are shown in Fig. 1. The observed enhanced radiation from the plage region is clearly evident on all three scans. The scan on September 26 was made at the time of the maximum of an importance 3 solar flare occurring in the plage region. The enhancement recorded on September 26 is about twice the enhancement for the two scans made on the day before and the day after the flare. This indicates that the enhanced radiation is from the flare.

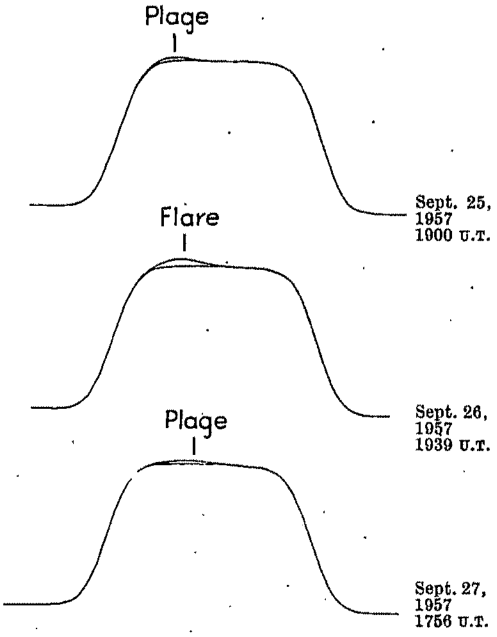

Fig. 1. 4·3-mm. solar scans across plage region and flare of importance 3. Upper curves, observed scans; lower, quiet sun scans for comparison

McCullough at the Naval Research Laboratory recorded the 9·4-cm. solar radiation on September 26, and Fig. 2 is his record of the burst observed coincident with the importance 3 flare. The increase in flux at 9·4 cm. was about 40 per cent at 1938. The observed increase at 4·3 mm. corresponds to a flux increase of 0·36 per cent with respect to the entire disk. Thus the per cent increase of flux at 4·3 mm. was about 1/100 of that at 9·4 cm.

The areas of the plage region before and after the flare and the area of the flare were determined from H-alpha photographs made with a flare patrol camera[2]. These areas were used to compute the average brightness of the plage and flare that would produce the observed enhanced radiation at 4·3-mm. wave-length. The average brightness temperature for the plage came out to be 8,100° K., which is to be compared with the 7,000° K. brightness temperature[1] of the quiet solar disk at 4·3 mm. The brightness temperature for the flare was 14,400° K. Neither the brightness temperature for the flare nor the plage is exceedingly high, and therefore it is fairly easy to explain the observed enhanced radiation as just thermal radiation from the flare area and from the plage area.

Tensile Strength of Indium

Eppelsheimer and Reitsma[1] have recently pointed out that a tensile strength of 7·99 tons/in.^{2} hitherto ascribed to indium containing 0·29 per cent impurities was really the value for gold containing 0·29 per cent indium. For this reason they redetermined the tensile properties of 99·97+ per cent indium, finding tensile strength 388 lb./in.^{2} and 70 per cent elongation.

About six years ago, Jaffee and Weiss[2] reported the tensile strength of pure indium (metal as annealed one week at 230–266° F.) as 380 lb./in.^{2}, elongation 22 per cent on 1 in. They make acknowledgment to Consolidated Mining and Smelting Co. of Canada, Ltd., for permission to publish, so presumably the indium used was derived from the latter, which also quotes these results in its pamphlet on indium.

Note added in proof. Since this was written an earlier determination has come to light. In 1943, A. H. Stang and B. L. Wilson[3] (Bureau of Standards) found a tensile strength of 430 lb./in.^{2} for 99·9 per cent metal from the Indium Corporation of America.

Photoconductivity and Crystal Size in Evaporated Layers of Cadmium Sulphide

THE photoconductive properties of evaporated layers of cadmium sulphide have been the subject of relatively few studies as compared with the number of those applied to single crystals. Aitchinson[1] showed some years ago that layers obtained by evaporation in a very good vacuum (better than 10^{-6} mm.) were photoconductive. His results were recently repeated by Nelson[2], who pointed out the influence of the chemical purity of the starting material. In general, evaporated layers acquire their optimum photoconductive properties only after an activation treatment which may be provided by heating in air[3] or heating in an inert atmosphere after covering by a thin evaporated layer of metal as was indicated by Veith[4].

During the investigation of this last process we observed a peculiar phenomenon of crystal growth in evaporated cadmium sulphide layers. The cadmium sulphide was deposited on glass plates the temperature of which could be controlled during the process. It was found that if the temperature was maintained at about 200° C. the layers were of microcrystalline nature and had a very well oriented structure: an X-ray diagram of such a layer, taken with a goniometer, shows only the 0002 lines and their higher orders. The diffraction lines are relatively sharp, but the Cu$K\alpha_1$, α_2 doublet is not resolved. That means that the individual crystals must have a size of the order of 1000 A. If such a layer is covered with a film of evaporated silver of thickness approximately equal to 100 A. and then heated to 500–600° C. in an inert atmosphere it frequently but not always happens that the layer recrystallizes and shows, after heat treatment, only the $1\bar{1}03$ or the $1\bar{1}05$ X-ray diffraction line. Furthermore, the X-ray diffraction lines are then very sharp and the Cu$K\alpha_1\alpha_2$ doublet is well resolved even at low angles.

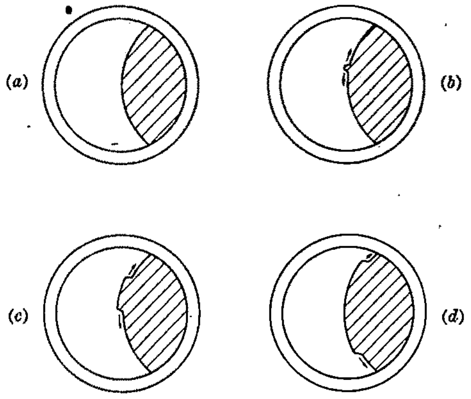

Fig. 1. Growth mechanism. The etched area represents a recrystallized region in which the direction of growth is from *a* to *d*

Cadmium sulphide having a hexagonal lattice, it is possible to observe the growth of the crystals in a glass furnace between two crossed polaroids. Under our experimental conditions the growth front velocity varied between 0·1 and 0·5 mm. per sec. The growth front does not progress as a whole; recrystallization is more or less a local phenomenon and it sometimes was observed that the recrystallization progressed in small bands perpendicularly to the motion of the growth front (Fig. 1). It is certain that the silver plays an active part in the process: samples partly covered by bands or dots of evaporated silver never showed any sign of recrystallization in the uncovered parts. Recrystallization was obtained with other substances, the first being copper the activity of which is similar to that of silver. The others are lead, indium, aluminium, bismuth, zinc and even zinc sulphide. The size of the crystals obtained with these last substances is relatively small, whereas those obtained with silver could be as large as the sample itself, that is, 12 mm. in diameter.

The photoconductivity of these layers seems to be very sensitive to traces of impurities, and the connexion between recrystallization and photoconductivity can only be expressed in a statistical form: seventy samples which had been activated in the same way were examined. Some of them were recrystallized, others not. The ratio of the electrical conductivity under an illumination of 100 lux to the dark conductivity was used as a quality factor. The

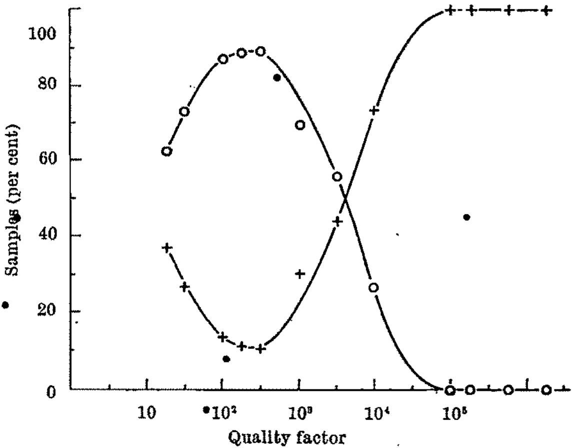

Fig. 2. Percentage of samples as a function of their quality factor. +—+, Recrystallized samples; O—O, unrecrystallized samples

experimental range of quality factors was from 1 to 10^6. This scale is divided into intervals, and in each interval one plots separately the per cent of recrystallized and unrecrystallized samples (Fig. 2). Good samples are found only among the recrystallized samples. Furthermore, a careful examination of the specimens indicates that the quality factor and the absolute intensity of the photocurrent are the highest in the samples with the largest and most perfect crystals.

Identity of Ions in Some Flames

Some results reported in a previous communication in *Nature*[1] have shown the possibility of mass spectrometric identification of the ions present in some flames. More results have now been obtained which suggest a comparison between different kinds of flames burning at a pressure of about 10 mm. mercury instead of the pressure of 40 mm. chosen in our earlier experiments.

The bare determination of the mass number of the observed peaks is not sufficient to identify unambiguously the corresponding ions; however, by burning partially deuterated fuel, the hydrogen content of the ions can be carefully checked.

The ions described here are given in sequence of decreasing abundance. The figures under the heading "Hydrogen content" are the number of hydrogen atoms contained in each ion; these figures are, of course, one unit less than the number of peaks into which the original single peak is split when partially deuterated fuel is burned. Furthermore, it was shown that the relative intensity of the split peaks corresponds fairly well to what can be estimated from the percentage of deuterium in the fuel molecule. All results reported here (Table 1) concern flames which are being propagated in undiluted mixtures rich in fuel (except when otherwise stated); the flames were kept as near as possible to the hole through which the ions are extracted.

From these results, the following conclusions may be derived: (1) There seems to be a tendency for H^+ to be attached to polar molecules such as H_2O, NH_3 and HCN. (2) NH_4^+ can be formed as soon as the flame is propagated in a mixture where nitrogen is a part of the fuel or of the oxidizer molecule. (3) Once too great an amount of NO is present in the burned gases, most of the ions are NO^+. This is probably due to the lower ionization energy of NO (charge transfer in the flame front).

This last point is confirmed by the following observation: peak intensities decrease when the ions are sampled at a larger distance ahead of the flame: the rate of this decrease is not the same for all ions and, in some cases, one observes first for NO^+ a slight increase after which, because of recombination, the normal decrease is observed.

Table 1

Mixture	Mass units	Hydrogen content	Identity of ion	Remarks
C_2H_2/O_2	19	3	H_3O^+	
	37	5	$H_5O_2^+$	Only in flames diluted with nitrogen and at a rather higher pressure (at least 25 mm. mercury)
	39	3	$C_3H_3^+$	Only in rich flames
	29	1	COH^+	
	30	0	NO^+	Does not appear when no nitrogen is added to the flame

The masses 19, 37 and 39 correspond to about 95 per cent of the total ion concentration.

Very weak peaks are noticed at masses 13, 14, 17, 18, 24, 26, 28 and 43 (less than 0·1 per cent).

Mixture	Mass units	Hydrogen content	Identity of ion	Remarks
C_2H_2/N_2O	30	0	NO^+	At least 90 per cent
	18	4	NH_4^+	
	19	3	H_3O^+	
	28	2	H_2CN^+	
	39	3	$C_3H_3^+$	Only in rich mixtures
	29	1	COH^+	
	43	?	?	Too weak to check hydrogen content

Very weak peaks at masses 26, 31, 41, 44 (less than 0·1 per cent).

Mixture	Mass units	Hydrogen content	Identity of ion	Remarks
CH_4/O_2	19	3	H_3O^+	
	29	1	COH^+	Only about 1 per cent
C_2H_2/O_2 with about 1 per cent NH_3				More or less the same mass spectrum as in the case of C_2H_2/N_2O flames; however, the NO^+ peak is relatively weaker.
C_2H_2/O_2 with about 2 per cent HCN				The ratio H_2CN^+/NO^+ is about the same in both cases, NH_4^+ is less important with the addition of HCN than of NH_3.

We have not systematically extended our investigations beyond 45 mass units. Some higher masses are reported by P. F. Knewstubb and T. M. Sugden[2]; in our low-pressure flames the corresponding peaks are absent or much weaker than those observed by these authors on flames burning at atmospheric pressure.

Gas Chromatograph as a Methanometer in the Coal Industry

Gas-solid chromatography has now found acceptance for the determination of hydrogen in mine atmospheres. The instruments developed for this purpose also give a complete separation of methane. An investigation was therefore undertaken to determine the possibility of using the existing instruments for routine or emergency estimation of methane in cases where the higher accuracy of the Haldane apparatus was not necessary, or when the use of volumetric combustion methods was not practicable. For routine use the gas chromatograph has the advantage of speed and specificity, and moreover it can be operated by semi-skilled personnel.

The apparatus used in these experiments was the gas chromatograph for the determination of hydrogen in mine airs, developed by the National Coal Board (North-Western Division) for use in its Area

Laboratories. This is similar to the instrument described by me in an earlier communication[1], using active carbon column packings and nitrogen as the carrier gas, and differing only in that while the columns and detector of the earlier instrument were maintained at 30° ± 0·05° C., in later instruments no thermostat was used, columns and katharometer being immersed in an oil-bath containing 6·5 l. of transformer oil. Even when room temperature is varying quite rapidly, the high thermal capacity of the oil-bath serves to maintain the temperature of the columns and katharometer reasonably constant during the short time required for the separation. After calibration with a standard methane/nitrogen mixture, a number of analyses may be carried out before re-standardization becomes necessary.

The experiments were carried out using a number of methane/nitrogen mixtures, with methane contents in the range 0·65–94·8 per cent. The composition of these mixtures was established from repeated volumetric combustion analyses using a Haldane apparatus, after dilution of the samples with the necessary volume of air. 10 ml. samples were taken for analysis by gas chromatography.

Plotting peak height against methane concentration, the curve shown in Fig. 1 was obtained. In the range of methane concentration 0–5 per cent the curve is nearly linear; from 5–45 per cent there is considerable curvature, while above 45 per cent the curve again becomes almost linear. The occurrence of two linear regions seems to follow from the variation of peak width with component concentration. Samples containing up to 5 per cent methane give peaks of practically constant width. Above 5 per cent, the methane peak 'tails', the peak width increasing rapidly with concentration up to about 45 per cent methane; further increase of methane concentration up to 95 per cent gives only a very slight increase in peak width, and the relationship between peak height and concentration is again linear, though the extrapolation of this line does not pass through the origin. The change in the shape of the methane peak with concentration is shown in Fig. 2. No theoretical explanation can be offered for the constant width of the peak for concentrations above 45 per cent. Further 'randomized block' experiments covering the concentration ranges 0–5 and 45–100 per cent confirmed the linearity in these regions, and indicated that the precision of a single determination in the 0–5 per cent range was ±0·08 per cent, and ±1·2 per cent in the 45–100 per cent range. Fortuitously, the methane/air mixtures, which are of the greatest importance in the coal industry, namely, mine airs and methane drainage gases, in general have methane contents lying within the linear regions. If peak areas rather than peak heights are measured, the response/concentration curve becomes almost linear over the whole range, but the precision is slightly less, because of additional error introduced in the measurement of the areas. Clearly, for the purpose of routine analysis, it is advantageous if measurement of peak height can be substituted for measurement of peak areas. Whichever measurement is taken, the method has considerable scope for the analysis of mine airs, including fire and methane drainage gases, since it provides a rapid and specific determination of both hydrogen and methane on one sample.

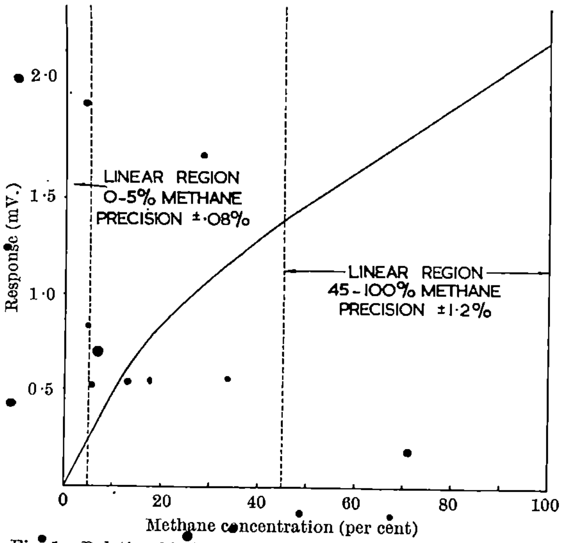

Fig. 1. Relationship between peak height and methane concentration

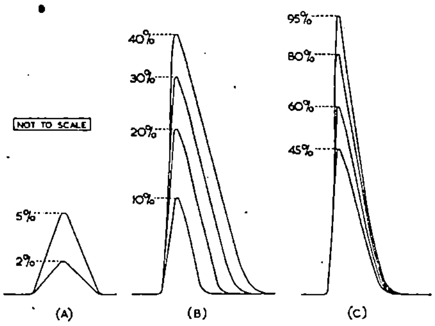

Fig. 2. Changes in peak shape with methane concentration. (*A*) shows constant peak width over range 0–5 per cent methane, (*B*) shows increase in peak width from 40 per cent, (*C*) nearly constant peak width above 45 per cent

The gas chromatograph appears to be a valuable analytical tool for the determination of methane in methane drainage gases on account of its specificity, since other hydrocarbon gases are frequently present; this makes a methane determination by the volumetric combustion method lengthy and of doubtful accuracy. In this connexion it may be noted that ethane, in amounts of 1–6 per cent, appears to be a normal constituent of methane drainage gases from collieries in Lancashire and North Wales, a notable exception being the gas from Point of Ayr Colliery, North Wales, which is free from hydrocarbons other than methane. As ethane is not eluted as a recognizable peak from carbon columns at room temperature, separation of ethane and hydrocarbons up to C_5 has been carried out on 3-m. columns of active alumina modified with paraffin wax, at temperatures between 25° C. and 60° C., using hydrogen as the carrier gas. A full account of this work will be published at a later date.

Acknowledgment is made to D. H. Ward for the statistical analysis of the experimental results.

Separation of Some Tobacco Alkaloids by Gas Chromatography

Gas chromatography has been employed in separating numerous types of compounds, but has not yet been applied to the alkaloids, a field where it might find particular utility. We wish to report preliminary results clearly indicating the usefulness of gas chromatography in the study of the tobacco alkaloids. Other families of alkaloids having slight volatility and good thermal stability may also prove to be separable under similar conditions.

For the stationary liquid phase we found certain polyglycols (Table 1) preferable to the less-polar materials, such as 'Apiezon' grease and the silicones, commonly used in high temperature work. The stability and non-volatility of the polyglycols are sufficient to permit continuous use of columns for several days without appreciable changes in their retention ability. The alkaloids were eluted in sharp, symmetrical peaks with columns containing the polyglycols.

Table 1

	Columns and conditions		
Liquid phase	Polyethylene glycol (*a*)	Polypropylene glycol (*b*)	Polybutylene glycol (*c*)
Temperature	190° C.	190° C.	180° C.
Helium flow (ml./min.)	48	45	50
	Retention time (min.)		
3-Pyridyl methyl ketone	4·3	4·3	3·1
3-Pyridyl ethyl ketone	5·3	6·1	5·0
3-Pyridyl *n*-propyl ketone	6·6	8·1	7·0
Nicotine	5·2	8·6	8·2
Nor-nicotine	12·3	16·1	14·3
Myosmine	13·4	16·4	14·7
Anabasine	13·8	19·4	18·1
Metanicotine	16·5	23·5	20·9
Nicotyrine	19·4	21·0	18·3
Cotinine	85	79	63

(*a*) Molecular weight, 20,000 (Dow Chemical Co.). (*b*) Molecular weight, 1,025 (Union Carbide Chemical Co.). (*c*) Molecular weight, 1,500 (Dow Chemical Co.).

The polyglycol columns exhibited good selectivity for the alkaloids, making possible the separation of most of the members of complex mixtures. This is seen from the retention-time data in Table 1. The elution sequence is identical on the polypropylene and polybutylene columns, although some relative differences in retention times are observable. A slightly different sequence was noted for the polyethylene glycol column. These effects are valuable in that a separation of two alkaloids difficult on one column may be feasible on another.

That the structure of the alkaloids had not been altered by the rather severe conditions of the gas chromatographic technique was established by obtaining ultra-violet absorption spectra for samples condensed from the gas stream as the elution peak for an alkaloid, run individually, was being recorded. In every case, the collected and starting compounds were identical. Paper chromatographic studies, using solvent systems *S*1 and *L*5 of Kuffner *et al.*[1], were also performed in some cases and verified this conclusion.

The Perkin–Elmer Vapor Fractometer, Model 154–*B*, modified to include a thermostat for the column chamber and a heater on the vent line from this chamber, was used in this study. Samples were 20λ aliquots of benzene solutions containing 5–10 mgm. per ml. of the alkaloids. Helium was used as carrier gas. The solid support was alkali-washed firebrick; liquid phases were placed thereon in the weight ratio of 1 to 4. Columns were U-tubes of 6 mm. outside diameter glass tubing, 1 m. long. The helium flow was determined at the vent with a soap-bubble meter at room temperature.

The alkaloid fraction of cigarette smoke is being investigated with the techniques described here. Results will be published in a subsequent paper.

We are indebted to the American Tobacco Company and to Drs. R. F. Dawson and R. N. Jeffrey for generous gifts of alkaloids. This work was supported by a grant from the Damon Runyon Memorial Fund.

Complex Phospholipids

Recent work has revealed the existence of hitherto unsuspected phospholipids in addition to the three major components, lecithin, phosphatidyl ethanolamine and phosphatidyl serine, and two minor components, sphingomyelin and phospho-inositide. Lea, Rhodes and Stoll[1], by chromatography on silicic acid, obtained lysolecithin and lysocephalin from egg yolk phospholipids, and Marinetti, Erbland and Kochen[2] have shown by paper chromatography that unidentified phospholipids were present in a number of tissues. This work is supported by the results obtained by Dawson[3] and Benson and Maruo[4]. Collins and Wheeldon[5], working with the N-2 : 4-dinitrophenylated and methylated derivatives of the phospholipids from rat and sheep brain and rat liver, have shown the presence of a fraction of the ethanolamine- and serine-containing phospholipids which corresponds neither to phosphatidyl ethanolamine nor to phosphatidyl serine. The present work is concerned with the presence of additional new and as yet unidentified compounds in this fraction.

Rat liver lipids, after N-2 : 4-dinitrophenylation and methylation as described by Collins and Wheeldon[5], were separated into polar and non-polar fractions by counter-current distribution in 85 per cent (v/v) aqueous ethanol-light petroleum. The non-polar fraction was further fractionated by chromatography on 'Hyflo-Supercel' (1 mgm. lipid to 2 gm. of adsorbent) and four materials containing phosphorus separated by elution with the solvent sequence, light petroleum, light petroleum-benzene mixtures, benzene, benzene–chloroform mixtures and chloroform. The characteristics of these four fractions are shown in Table 1.

Chromatography of the polar fraction led to its decomposition, but counter-current distribution enabled the isolation of three dinitrophenyl-containing compounds and certain of their properties have been determined (Table 2). One of these compounds has been isolated in sufficient quantity for a full analysis and appeared to be homogenous as shown by the distribution curve. Sheep brain lipids were found to be the best source for its isolation.

Determination of the molecular weight by an isopiestic method[6] and by the depression of the freezing point in cyclohexane indicated values of

Table 1. Properties of the Phospholipids in the Non-Polar Fraction of Rat Liver Lipids

	X	*Y*	*Z*	Phosphatidyl ethanolamine and serine
Partition coefficient in:				
Methanol-petroleum (100–120° C.)	3·6	1·5	0·9	0·6
85 per cent (v/v) aqueous ethanol-light petroleum	12·0	4·7	—	1·6
Absorption maximum	none	none	410 mμ	328 mμ
Phosphate as percentage of the total lipid phosphate	0·78	0·33	1·15	9·40

2030 and 2200 respectively. Elementary analysis assuming two atoms of phosphorus per molecule indicated the empirical formula $C_{105\pm1}H_{183\pm2}N_6O_{29}P_2$. The substance contained no free amino-groups, no aldehydogenic groups and no sulphur. The absorption maximum, due to the dinitrophenyl group, was at 333–335 mμ (E = 17,200).

The material was hydrolysed by refluxing with ethanolic 2 *N* hydrochloric acid for 3 hr. and the hydrolysate divided into three fractions: (1) light petroleum-soluble; (2) insoluble in light petroleum but soluble in diethyl ether; (3) insoluble in diethyl ether but soluble in water.

Fraction (1) was refluxed with 2 *N* potassium hydroxide (1 : 1 water-ethanol by volume) for 3 hr. and the unsaponifiable material separated by extraction into diethyl ether; analysis of this material, which constituted 23 per cent of the complex phospholipid and on which a Liebermann–Burchard test was negative, showed the presence of 1·04 hydroxyl-group/mole. The fatty acids were recovered by acidification of the soaps and extracted into diethyl ether, and yielded 1·92 moles/mole.

Fraction (2) contained dinitrophenyl-ethanolamine (0·95 mole/mole) and dinitrophenyl-serine (0·05 mole/mole) and no other material containing dinitrophenyl as shown by paper chromatography using the solvent systems described by Collins and Wheeldon[7].

Fraction (3) contained 1·95 mole phosphorus/mole and less than 5 per cent was in the form of inorganic phosphate. On paper chromatography only one phosphate spot could be detected and this was identical in behaviour with glycerol-1-phosphate in five solvent systems. It was thus concluded that 2 moles/mole of glycerol-1-phosphate were present. Paper chromatography also showed the presence of choline (0·96 mole/mole) and a reducing sugar (0·96 mole/mole) which was either glucose or galactose.

Fraction (3) contained 0·99 mole/mole and fractions (1) and (2) together contained 1·09 mole/mole of unidentified compounds containing nitrogen. The presence of these materials in sheep brain complex phospholipid indicates that similar complex phospholipids may account for some of the unidentified compounds containing nitrogen that have been described in phospholipids in other tissues[8].

Table 2. Properties of the Amino-Phospholipids in the Polar Fraction of Rat Liver and Sheep Brain Lipids

Fraction	1	2	3
Partition coefficient in carbon tetrachloride/methanol/water (62 : 35 : 3·15 v/v/v) (ref. 9)	1·0	2·5	8
Carbon tetrachloride/chloroform/methylene chloride/methanol/water (25 : 15 : 10 : 40 : 10 by vol.) (ref. 11)	0·2	0·5	4
Amino-nitrogen as percentage of the total amino-nitrogen in rat liver lipids	5	35	11
Amino-nitrogen as percentage of the total amino-nitrogen in sheep brain lipids	25	13	16

This complex phospholipid from sheep brain may consist of one molecule of lysolecithin and one molecule of lysophosphatidyl ethanolamine joined together by a compound containing no phosphorus made up of the two unidentified residues containing nitrogen, the sugar and the fatty alcohol. However, the precise nature of this material cannot be determined without further chemical studies.

A full description of this work will be published elsewhere.

Thyroxine-binding Protein in the Serum of Rabbit Fœtuses

Human serum contains a thyroxine-binding protein which moves to a position between the α_1 and α_2 globulins on paper electrophoresis in a barbiturate buffer[1]. We have investigated the thyroxine-binding power of maternal and fœtal serum taken from pregnant rabbits at different stages of pregnancy. L-Thyroxine, labelled with iodine-131 and having a specific activity of 5 μc./μgm., was added to samples of the serum to give a concentration of about 0·05 μc./ml. of serum. Half to one hour later, 0·02 ml. of the serum was put on to a strip of Whatman No. 3 *MM* filter paper and electrophoresis carried out as described elsewhere[2], using a barbiturate buffer at *p*H 8·6 and ionic strength 0·1. After the current had been passed for 18 hr. the papers were dried and the position of the radioactivity determined by means of a continuously recording scanner. The bands of protein on the paper were then stained with lissamine green.

At all the stages of pregnancy examined, the radioactivity in the maternal serum was confined mainly to a single peak between the albumen and the α_1 globulin (Fig. 1c). In some cases there were also small peaks near the region of the β-globulin and at the position of the albumen. In the fœtal sera the protein composition, as revealed by the intensity of staining, varied according to the age of the fœtus. At the 19th day of pregnancy the albumen band was much weaker than that in the mother, the α_1 was absent and the α_2 was stronger than the β-band. As the age of the fœtus increased, the relative intensities of the different bands came to resemble more closely those in the mother. Before the 30th day the fœtal serum showed no radioactivity at the position corresponding to maternal thyroxine-binding protein, but at all stages from the 19th to the 28th days there was a single peak between the

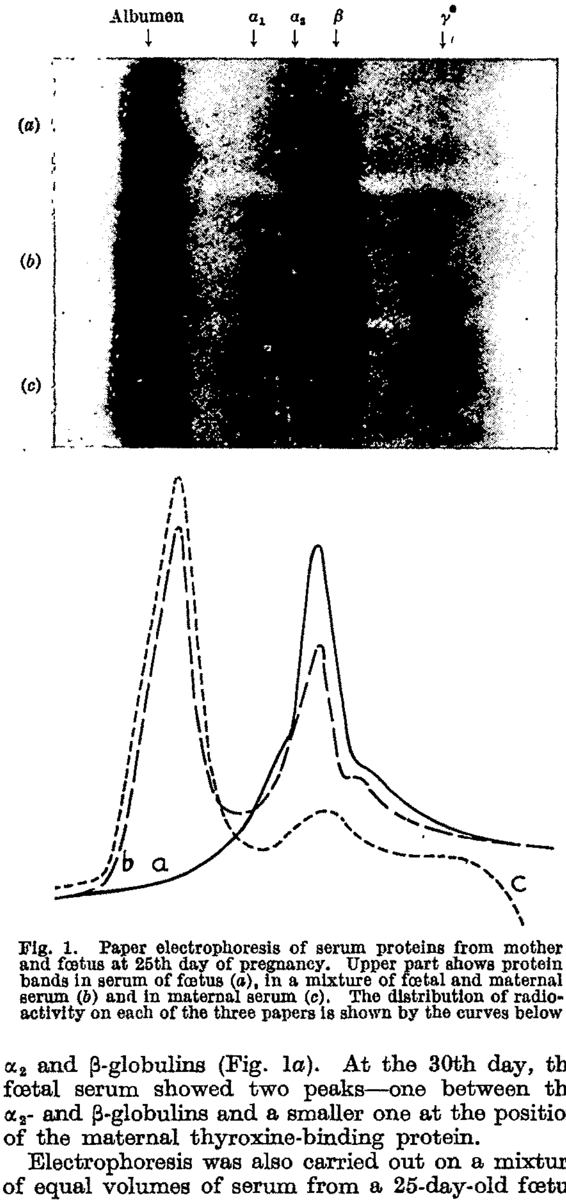

Fig. 1. Paper electrophoresis of serum proteins from mother and fœtus at 25th day of pregnancy. Upper part shows protein bands in serum of fœtus (*a*), in a mixture of fœtal and maternal serum (*b*) and in maternal serum (*c*). The distribution of radioactivity on each of the three papers is shown by the curves below

α_2 and β-globulins (Fig. 1*a*). At the 30th day, the fœtal serum showed two peaks—one between the α_2- and β-globulins and a smaller one at the position of the maternal thyroxine-binding protein.

Electrophoresis was also carried out on a mixture of equal volumes of serum from a 25-day-old fœtus and the serum from its mother, after labelled thyroxine had been added to the mixture. Two separate peaks of radioactivity were observed—one between the α_2- and β-globulins and the other at the position of the maternal thyroxine-binding protein (Fig. 1*b*).

The relative amount of thyroxine bound by the fœtal and maternal binding proteins at different stages of pregnancy was studied *in vitro* by comparing the heights of the two peaks of radioactivity in mixtures of fœtal and maternal serum. At increasingly early stages of pregnancy there was a decrease in the ratio of the height of the fœtal to that of the maternal peak of radioactivity. At the 19th day radioactivity at the position of the fœtal binding protein was scarcely discernible in a mixture of the fœtal and maternal sera; by the 28th day the height of the peak between the α_2- and β-globulins was almost half as high as that behind the albumen.

We conclude that the specific thyroxine-binding protein of adult serum is not present in the fœtus until about the 30th day, but that the fœtal serum contains one or more binding proteins with an electrophoretic mobility intermediate between that of the α_2- and β-globulins. Binding power is present in the serum of 19-day-old fœtuses, but at this stage of pregnancy it is much weaker than that in the maternal serum. By the end of pregnancy, the binding power of the fœtal serum is nearly half as great as that of the mother's serum.

It has been shown that when thyroxine is injected into the maternal circulation in early pregnancy, very little appears in the fœtal circulation[3,4]. If, however, the injection is made at later stages of pregnancy, increasing amounts of thyroxine reach the fœtal circulation[5]. This apparent increase in the permeability of the placenta to thyroxine may be explained by the increasing binding power of the fœtal serum. Thus, if the placenta were at all times permeable to unbound thyroxine, but impermeable to bound thyroxine, thyroxine injected into the mother should distribute itself between the maternal and fœtal circulations in the ratio of their respective binding powers.

An Indirect Action of Angiotensin I on Smooth Muscle

THE stimulatory action of angiotensin I (angiotonin, hypertensin) on isolated ileal segments was investigated to determine whether this action is entirely a direct one on the muscle fibre. Some evidence for an indirect action was obtained mainly by the use of botulinum toxin, which causes functional cholinergic denervation of the muscle.

The tissue was left in contact for 30 min. with 10 mgm. of toxin type *A* (equivalent to $2\cdot5 \times 10^7$ mouse *LD*50) or for 60 min. with 100 mgm. of toxin type *D* (equivalent to 3×10^6 mouse *LD*50) in 2–3 ml. bathing fluid at 37° C. The contractions of the longitudinal muscle of rabbit ileal segments in a 10 ml. bath to doses of 0·15–0·2 μgm. acetylcholine, 5–10 μgm. nicotine and 0·5–3·0 Indianapolis units of angiotensin I (4 min. contact), which were equiactive before toxin treatment, were compared after toxin. In four out of four experiments the responses to acetylcholine remained unaltered, those to nicotine were abolished and those to angiotensin were markedly reduced or abolished. Moreover, in four out of four preparations without toxin treatment, the addition of the true cholinesterase inhibitor *BW* 284*C*51 (2×10^{-7} gm./ml.) potentiated the responses to both nicotine and angiotensin and, in three out of three experiments, hexamethonium (3×10^{-4}) reduced the responses to angiotensin by an average of 50 per cent although those to acetylcholine control doses were not reduced.

On the only occasion on which it was tested, type *D* toxin did not alter the slow contraction of guinea pig ileum to angiotensin; however, it completely abolished the quick contraction which occurred on washing out angiotensin from the bath. No similar quick contractions on washing out angiotensin were observed in rabbit ileal preparations.

Thus it appears that at least part of the action of angiotensin I on some isolated ileal preparations is indirect, being mediated through cholinergic neurones.

We wish to thank Dr. O. M. Helmer of Indianapolis for a supply of angiotensin I and Dr. J. Keppie of Porton for the botulinum toxin.

Sorbitol Dehydrogenase in Spermatozoa

It has been shown previously that the addition of sorbitol to actively respiring suspensions of washed, motile ram spermatozoa causes an increase in the consumption of oxygen, accompanied by an oxidative conversion of sorbitol to fructose and followed by the ærobic glycolytic breakdown of fructose to lactic acid[1]. More recently, it was established that sorbitol, like fructose, actually occurs as a normal constituent in the seminal plasma of ram, bull, man and certain other species[2]. These findings make it highly probable that lactic acid, which accumulates in normal semen on aerobic incubation *in vitro*, is in fact in part the product of direct glycolysis from preformed seminal fructose, but partly also originates from the metabolism of sorbitol *via* fructose.

In the course of experiments designed to elucidate the mechanism of sorbitol oxidation it was noted that not only are ram spermatozoa able to oxidize sorbitol, either in the presence of molecular oxygen or artificial electron acceptors, such as triphenyltetrazonium chloride, but that they are also capable of reducing fructose to sorbitol, both aerobically and anaerobically. The reduction of fructose to sorbitol probably explains our observation that the content of sorbitol in freshly ejaculated ram semen is apt to increase on standing. When instead of fructose, glucose is added to a washed sperm suspension, a reduction to sorbitol also occurs, but at a much lower rate.

In an attempt to extract the enzyme responsible for the oxido-reduction of sorbitol to fructose, various methods were used such as grinding the sperm with glass powder, freezing and thawing, shaking in a Mickle disintegrator, preparation of acetone-powder and treatment with hypotonic solutions and detergents. None of these procedures, however, yielded a positive result. A partial disintegration of spermatozoa, accompanied by the appearance of small quantities of a soluble enzyme, was achieved by the use of the Mullard magnetostriction transducer Type *E*7590*B* at 500 watts and 25 kc./s. for 10 min. Finally, however, a method has been elaborated which makes it possible to prepare the enzyme in a completely soluble form. This was accomplished by applying a treatment similar to that developed by McIlwain for the preparation of cell-free extracts from certain bacteria[3]. The well-washed and sharply centrifuged ram spermatozoa were ground with lavigated aluminium oxide (Hopkin and Williams Ltd.) and this was followed by extraction with cold 0·025 *M* phosphate buffer, *p*H 7·3. On centrifugation of the extracts, first in a refrigerated M.S.E. centrifuge and afterwards in a 'Spinco' preparative centrifuge (for 45 min. at 40,000 r.p.m.), clear solutions were obtained, approximately 30 ml. for each 10 ml. of ram semen used. The solutions thus obtained showed on spectrophotometric examination a ratio of about 0·5 between light extinction at 280 (E_{280}) and 260 mμ (E_{260}). Treatment with protamine sulphate produced a voluminous precipitate which, however, could be removed without affecting the content of the enzyme. The filtrates, exhibiting a markedly higher ratio between E_{380} and E_{260}, were used for further fractionation.

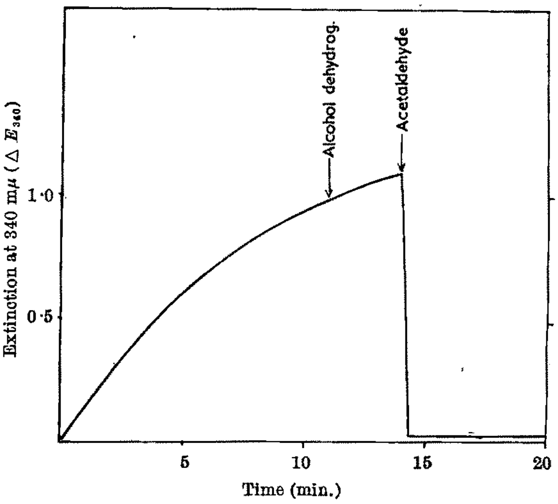

Fig. 1. Oxidation of sorbitol by the sorbitol dehydrogenase obtained from ram spermatozoa. The oxidation of sorbitol was followed by measuring spectrophotometrically the extinction at 340 mμ, due to reduced diphosphopyridine nucleotide, in a 1-cm. cuvette. The reaction mixture (3 ml.) contained 1 μmole diphosphopyridine nucleotide, 100 μmoles of sorbitol, 60 μgm. enzyme, and 0·033 *M* tris buffer, *p*H 8·6. The control mixture, from which sorbitol was omitted, did not reduce diphosphopyridine nucleotide. The re-oxidation of reduced diphosphopyridine nucleotide was carried out by the addition of 50 μgm. of crystalline alcohol dehydrogenase prepared from yeast and 80 μmoles of acetaldehyde

The soluble enzyme prepared from spermatozoa required diphosphopyridine nucleotide (DPN) for the following reversible reaction :

$$\text{sorbitol} + \text{DPN}^+ \rightleftharpoons \text{fructose} + \text{DPNH} + \text{H}^+$$

Triphosphopyridine nucleotide was unable to replace diphosphopyridine nucleotide in the above reaction. The rate at which diphosphopyridine nucleotide was reduced is shown in Fig. 1, whence it can also be seen that reduced diphosphopyridine nucleotide formed during the oxidation of sorbitol could be rapidly re-oxidized by the addition of acetaldehyde and the diphosphopyridine nucleotide-specific alcohol dehydrogenase from yeast. The amount of keto-sugar formed from sorbitol in the presence of the sperm enzyme was determined colorimetrically[4] and found to be slightly less than the stoichiometrical equivalent of reduced diphosphopyridine nucleotide.

The partially purified sorbitol dehydrogenase prepared from spermatozoa appears to be similar in its mode of action to the enzymes previously obtained from the rat liver[5] and male accessory organs[6,7]. At the optimal *p*H (8·6) the observed zero-order rate of the oxidation catalysed by the sperm enzyme was highest with D-sorbitol and decreased in the order L-iditol > D-xylitol > D-ribitol > D-mannitol. Glycerol, *meso*-inositol, *i*-erythritol and L-arabitol were not oxidized. As regards the reverse reaction, namely, the reduction of various sugars to the corresponding polyols, only fructose, and to a smaller extent, sorbose, were reduced. D-Glucose, D-mannose, D-ribose and 2-desoxy-D-glucose were not reduced, while L-xylose was reduced only very slightly.

The chemical equilibrium in the oxido-reduction shown by the equation favours much more the formation of sorbitol from fructose than the reverse process. In intact spermatozoa, however, the steady state of the reversible conversion of sorbitol to fructose must depend closely on the actual ratio between diphosphopyridine nucleotide and its reduced form present within the sperm cells. This ratio in turn must be related to the rates at which the various metabolic processes catalysed by diphosphopyridine nucleotide proceed in the semen. Among the oxidizable substrates present in semen, fructose and sorbitol occur in particularly large but, at the same time, variable concentrations. It is conceivable, therefore, that the respective levels of fructose and sorbitol in semen influence the ratio between the oxidized and reduced form of diphosphopyridine nucleotide as governed by the sorbitol dehydrogenase in spermatozoa.

We wish to thank Dr. R. Davies for help in performing experiments with the magnetostriction transducer, Dr. A. Walton for collection of semen, and Drs. F. Isherwood and N. K. Richtmyer for gifts of iditol.

Specificity of Agglutinins in Milk

Heinemann and Glenn[1] observed that certain bacteria were agglutinated in milk serum and concluded that this was possibly related to the germicidal action of milk. Chambers[2] made similar observations but could find no correlation between agglutination and germicidal action. Hobbs[3] examined a variety of milk organisms and attributed the clumping effect of milk on some of them to agglutinins which were probably non-specific. More recently, Wright and Tramer[4] demonstrated that certain organisms noted for slow acid production in activity tests of cheese starters were agglutinated in heat-treated milk. The lag in acid production was shown to be due not to agglutination but to the removal of the agglutinated organisms by the rising cream.

A number of fast and slow acid-producing streptococcal cultures were examined in this Laboratory for agglutination in raw whole milk, and in all cases the 'slow' cultures were shown to be agglutinated. To establish whether agglutination was specific, absorbing antigens were prepared by sterilizing cultures of the test organisms in papain-digested milk with ethylene oxide. After centrifuging, the absorption test was carried out by resuspending the cells in low-count raw whole milk and incubating at 52° C. for 1 hr. These milks were then inoculated at the rate of 10 per cent with standardized inocula of the test organisms and acid production determined after incubation at 30° C. for 6 hr. by titration with *N*/9 sodium hydroxide to the phenolphthalein end-point. Specificity of agglutination was further demonstrated by a ring test using coloured antigen[5]. Results are shown in Table 1.

Table 1. SPECIFICITY OF CERTAIN AGGLUTININS IN MILK

Medium	Lactic acid (per cent)				Ring test	
	*C*10 Fast strain	*ML*1 Slow strain	*KH* Slow strain	*DR*7 Slow strain	*C*10	*ML*1
Autoclaved whole milk	0·82	0·66	0·78	0·75	—	—
Raw whole milk (RWM)	0·89	0·33	0·42	0·34	—	+
RWM plus absorbing antigen :						
*C*10	0·89	0·38	0·52	0·37	—	+
*ML*1	0·85	*0·69*	0·50	0·38	—	—
KH	0·86	0·40	*0·66*	0·36		
*DR*7	0·85	0·34	0·48	*0·44*		

The marked increase in acid production by the slow cultures *ML*1 and *KH* when grown in milk previously absorbed with homologous antigen is clear evidence of specificity. The relatively small increase in the case of *DR*7 may be due either to a high agglutinin titre or incomplete absorption by the added antigen. All the slow cultures show a small non-specific increase in acid production in milk treated with absorbing antigen. This, however, is of a quantitatively lower order than that due to specific absorption.

Full details of this work will be published elsewhere.

My thanks are due to Prof. J. M. Vincent and Dr. Y. T. Tchan for their advice, and to Miss Anne Curley for technical assistance.

Vitamin B_{12} and Cobalt Concentrations in Livers from Healthy and Cobalt-deficient Lambs

During field investigations into cobalt deficiency we collected pasture samples from experimental paddocks at intervals for cobalt analyses, and at the end of the trials made comparisons of the vitamin B_{12} and cobalt concentrations in the livers of healthy lambs not given cobalt, cobalt-dosed lambs, and other groups showing various stages of cobalt-deficiency disease. Results are shown in Table 1.

Assessments of the cobalt status of pastures were based on a previously estimated minimal level considered necessary to satisfy the cobalt requirement

Table 1

Group	Cobalt status of pastures	Lamb data				Liver determinations					
		No. in group	Cobalt dose	Clinical state*	Stage of deficiency*	Vitamin B_{12} (μgm./gm. fresh tissue)		Cobalt (μgm./gm. dry weight)		B_{12} Co/total Co (ratio)	
						Range	Mean	Range	Mean	Range	Mean
A	Adequate throughout	12	None	Normal	Healthy	0·39–1·1	0·65	0·08–0·16	0·11	0·7–1·0	0·8
B	Low, increasing to adequate	10	7 mgm./lamb/week	Normal	Healthy	0·32–0·96	0·58	0·27–0·60	0·35	0·1–0·5	0·3
C	Low, increasing to adequate	11	None	Normal†	Recovered	0·19–0·60	0·31	0·05–0·12	0·08	0·4–0·9	0·6
D	Low throughout	15	None	Unthrifty	Moderate to severe	0·026–0·097	0·062	0·02–0·06	0·03	0·1–0·6	0·4
E	Low throughout	10	None	Moribund or dead	Extreme	0·008–0·068	0·036	0·02–0·08	0·03	< 0·1–0·4	0·2

* At slaughter or death. † Unthrifty two months previously.

of lambs[1]. The stage of deficiency for each group was assessed partly from pasture cobalt status but mainly from changes in weight or deaths. Vitamin B_{12} was extracted from livers by steaming with cyanide[2] and assayed with *Lactobacillus leichmannii*[3]. Cobalt concentrations in pasture and liver samples were determined by a nitroso-*R*-salt colorimetric method[4]. B_{12} cobalt/total cobalt ratios were calculated from vitamin B_{12} values converted to a dry-weight basis and the cobalt content (4·3 per cent) of the vitamin.

Results for groups *A* and *B* show that vitamin B_{12} concentrations in the livers of healthy lambs exceeded 0·30 μgm./gm. Since lambs in group *C* acted as controls to those in group *B* it is apparent that cobalt dosing approximately doubled the mean vitamin B_{12} concentration. From results for group *C* it appears that a mean vitamin B_{12} value of about 0·30 μgm./gm. can be consistent with a recent history of cobalt-deficiency disease. Results for groups *D* and *E* show that definite cobalt deficiency disease was associated with livers in which vitamin B_{12} concentrations were less than 0·10 μgm./gm. Although the ranges of vitamin B_{12} values for groups *D* and *E* overlapped, the mean for the latter group was only about half that for the former. Corresponding mean cobalt values were, however, the same for both groups. This suggests that vitamin B_{12} assays reflect more closely than do cobalt estimations differences between acute cobalt deficiency causing death and lesser degrees of deficiency.

B_{12} cobalt/total cobalt ratios for livers from group *A* show that most, and in some cases virtually all, of the cobalt in the livers of healthy lambs not receiving cobalt was in the form of vitamin B_{12}. In contrast, most of the cobalt in the livers of cobalt-dosed lambs (group *B*) tended to be in some form other than vitamin B_{12}. This seems best explained as due to inability of the rumen organisms to convert more than a small fraction of the dosed cobalt to vitamin B_{12}. A comparison of the ranges and means of B_{12} cobalt/total cobalt ratios for livers from groups *C*, *D* and *E* with corresponding results for group *A* suggests that cobalt deficiency results in a greater reduction of vitamin B_{12} cobalt than of non-vitamin B_{12} cobalt and that the magnitude of this effect is dependent upon the severity of the disease. Similar results from British work (Phillipson, A. T., Porter, J. W. G., Ford, J. E., and Holdsworth, E. S., private communication) support this conclusion.

Details of these experiments and of others concerning the diagnostic use of vitamin B_{12} determinations will be submitted to the *New Zealand Journal of Agricultural Research* for publication.

Ingestion of Ethylenediaminetetraacetic Acid and the Effect on Life Span of Irradiated and Control *Habrobracon* Females

The effect of chelating agents on recovery and longevity of irradiated animals has aroused considerable interest. Versene-type compounds are used for the decontamination of radioactive areas and internally for treatment of poisoning by heavy metals[1,2]. Mouse injections have resulted in improved post-irradiation survival[3], whereas cytological studies on plant cells have demonstrated that treatment with ethylenediaminetetraacetic acid (EDTA) prior to irradiation increases the yield of radiation-induced chromosome aberrations[4].

During a study of the genetic damage induced in the reproductive tissues of *Habrobracon* females by chelating agents and X-irradiation[5], considerable information was obtained on the life-span of treated females. The results of five such experiments will be reported here.

Freshly eclosed virgin *Habrobracon* females were starved for 3–5 days prior to feeding, or until dorso-ventral flattening of the abdomen was clearly visible. Groups of females were then fed either from a saturated sugar solution (controls), or from a stock solution of the disodium salt of ethylenediaminetetraacetic acid (0·1 *M*), which was further diluted with saturated sugar solution to ensure palatability. After single feedings, females were placed in Stender dishes and provided with host larvæ of *Ephestia kuhniella*, which the females parasitize. Host larvæ were replenished daily. Females were maintained under optimum conditions without further treatment for the remainder of their life-span.

Table 1. EFFECT OF INGESTED ETHYLENEDIAMINETETRAACETIC ACID AND X-IRRADIATION ON MEAN LIFE-SPAN OF *Habrobracon*

Experiment	Treatment	Mean longevity (days)	Standard error of mean.
A	Controls	27·5	1·94
	2,500 r.	27·1	2·08
	0·09 *M* EDTA	16·3	2·74
	Both*	9·11	2·82
B	Controls	22·8	2·75
	2,500 r.	22·0	1·08
	0·075 *M* EDTA	16·5	2·37
	Both*	12·4	2·49
C	Controls	24·1	1·85
	1,530 r.	25·1	0·34
	0·075 *M* EDTA	10·03	1·55
	Both*	9·82	0·44
D	Controls	22·6	1·71
	2,500 r.	19·9	2·84
	0·075 *M* EDTA	6·5	4·11
	Both*	10·1	1·75
E	Controls	25·7	1·3
	0·075 *M* EDTA	12·4	1·9
	0·025 *M* EDTA	21·0	1·5

* 'Both' indicates combined EDTA + X-ray treatment.

Results are shown in Table 1. It is apparent that X-rays had no effect on the reduction of life-span below that of the controls. Previous studies[6] have shown that *Habrobracon* females are highly radio-resistant when life-span reduction is measured. However, ethylenediaminetetraacetic acid feeding alone consistently decreased the average life-span of females below that of controls in every experiment. This difference is highly significant. Irradiation in addition to ethylenediaminetetraacetic acid ingestion tends to lower the life-span even more (experiments *A* and *B*), but the difference between irradiated and non-irradiated groups, both fed ethylenediaminetetraacetic acid, is not significant. It appears that the ethylenediaminetetraacetic acid meal is the most important determining factor in the reduction of life-span.

Following an ethylenediaminetetraacetic acid meal the death toll is greatest during the first few days. In order to differentiate between a poisoning effect and a true reduction of average life-span, all the results reported in Table 1 for control and ethylenediaminetetraacetic acid-fed females were recalculated omitting deaths occurring during the first two days after treatment. Results of such calculations indicate that the life-span of ethylenediaminetetraacetic acid-fed *Habrobracon* females is still significantly lower than that of control females. Thus ethylenediaminetetraacetic acid feeding does not act as a poison resulting in the death of a large number of treated animals during the first day and having no effect on the survivors of the first 48 hours, but rather it reduces the life expectancy of adult females at all times during the life-span.

Each of the 75 females comprising experiment *E* were weighed before and after feeding on a Roller–Smith precision balance. The amount of food ingested ranged from 0·015 mgm. to 0·505 mgm. Correlation coefficients (r values) for the relation between the amount ingested and the subsequent life-span showed there was no significant correlation ($r = -0·3041$) between the amount ingested and life-span in the group fed with 0·075 *M* ethylenediaminetetraacetic acid. In the group fed with 0·025 *M* ethylenediaminetetraacetic acid there was a slight positive correlation between the amount ingested and the life-span ($r = 0·4903$). This may be attributed to the fact that the most avid eaters are generally more vigorous. It is important to note that concentrations of ethylenediaminetetraacetic acid as low as 0·025 *M* will reduce the average life expectancy of a group of *Habrobracon* females.

The cause of death is unknown, but it seems unlikely that it resulted from chromosomal effects since, unlike vertebrates, adult insects are not dependent upon continued mitotic activity for the maintenance of the life processes. Ethylenediaminetetraacetic acid is known to alter or inactivate enzymes which are involved in oxidative or phosphorylative metabolism[7,8]. Many enzymes have metal ions as co-factors, and it is likely that chelation of metal ions by ethylenediaminetetraacetic acid would result in death due to metabolic failure.

Observations on a large number of females indicate that death subsequent to an ethylenediaminetetraacetic acid meal follows a pattern of progressive inactivation. Movement and activity are often noticeably decreased within a few hours after feeding. Once the female becomes inactive, recovery has not been observed, and death is inevitable. Females may remain in a quiescent, coma-like stage for as long as 12–24 hours before probing fails to elicit further response.

Ingested ethylenediaminetetraacetic acid enhances the radiation effect when fertility or dominant lethals are the criterion of damage[5], but the combination of treatments does not shorten the life-span in a synergistic manner.

This investigation was supported by a fellowship (*AF*–6540–*C*) from the National Institutes of Health, Public Health Service.

Phenylketonuria in the Rat associated with Decreased Temporal Discrimination Learning

IN the course of other investigations[1] in which tyrosine was injected intraperitoneally it was noted that the level of phenylalanine hydroxylase in the liver of rats was diminished to about one-third the normal value. Since tyrosine added *in vitro* does not inhibit this enzyme activity[2], the results were taken as evidence of product inhibition of enzyme synthesis. It was reasoned that added dietary tyrosine would decrease the enzyme formation and therefore lower the amount of phenylalanine being oxidized to tyrosine; the excess phenylalanine would then be transaminated to phenylpyruvate. Other workers[3] had already shown that phenylalanine added to liver slices would also inhibit the oxidation of tyrosine to acetoacetate and fumarate. It seemed worth while therefore to feed various combinations of tyrosine and phenylalanine in order to evaluate metabolic alterations in the rat. Initial experiments with commercial rat food plus 5 per cent L-tyrosine and 5 per cent DL-phenylalanine resulted in the death of newborn or suckling animals when this diet was fed to the pre-parturient and lactating mothers. The same diet caused death when fed to 21-day-old animals, although animals of the same age grew normally when fed 5 per cent of either amino-acid alone. Reduction of the levels to 2·5 per cent of each amino-acid (and in a later experiment to 3·75 per cent each) caused no difficulty since animals fed this diet gained weight at a rate comparable to that of rats on the commercial diet alone. The methods used for the amino-acid analyses and for enzyme assays have been previously listed[1]. The urinary and blood data are given in Table 1, and the enzymatic data concerned with phenylalanine and tyrosine metabolism are given in Table 2.

The enzymatic results substantiate the initial hypothesis that tyrosine feeding inhibits the production of phenylalanine hydroxylase. The decrease of phenylalanine hydroxylase in animals on the high phenylalanine diet may also in part be explained by the marked inhibition of the activity of this enzyme by high levels of phenylalanine[2]. The tyrosine transaminase activity was measured at a time when the initial increase in activity to be expected on a high tyrosine diet had already subsided[4]. The values for tryptophan peroxidase-oxidase and histidase, two amino-acid catabolizing enzymes which have no connexion with phenylalanine or tyrosine metabolism, were substantially the same in all groups of experimental and control animals.

It had been shown by Linn and Knox[4] that in the case of experimental alcaptonuria produced by the feeding of 5 per cent L-tyrosine in the diet the effects were transitory and lasted for only one month, after which time the excretion of homogentisate fell off. It would appear from our data on urine that the excretion of phenylpyruvate was similar to that of homogentisate and that the effect was maximum one month after the diet was started. In most of our experiments the urines were collected two to three months after initiation of the abnormal diets, so that we may have missed the period of even greater effect. Nevertheless, significantly higher amounts of phenylpyruvate and homogentisate were excreted by most of the experimental animals as compared with the controls.

Table 1

Diet	Plasma (mgm./100 ml.)		Total urinary excretion (mgm./day)	
	Tyrosine	Phenylalanine	Phenylpyruvate	Homogentisate
Normal (5)*	2·5	1·6	1·2	0·1
5 per cent L-tyrosine (5)	3·4	1·3	0·8	0·4
5 per cent DL-phenylalanine (5)	4·8	2·8	19·0	2·8
2·5 per cent each L-tyrosine and DL-phenylalanine (5)	7·4	2·8	3·9	0·9
3·75 per cent each L-tyrosine and DL-phenylalanine (5)†	—	—	54·6	59·8

* The numbers in parentheses denote the number of animals in each group.

† The urines from this group of animals were collected one month after being placed on the experimental diet, while the urines of the other groups were collected after two to three months on the diet (see text).

Table 2

Diet	μMoles product formed per gm. dry weight of liver per hr. at 38° C.			
	Tyrosine (α-ketoglutarate) transaminase	Phenylalanine (pyruvate) transaminase	Phenylalanine (α-ketoglutarate) transaminase	Phenylalanine hydroxylase
Normal (5)*	466±67†	313±29	325±37	24·9±4·4
5 per cent L-tyrosine (5)	313±46	381±24	386±37	0·9±0·9
5 per cent DL-phenylalanine (5)	301±57	348±38	345±21	1·9±0·4
2·5 per cent each L-tyrosine and DL-phenylalanine (5)	694±88	304±45	422±37	8·1±1·1

* The numbers in parentheses denote the number of animals in each group.

† Standard error of the mean.

In phenylpyruvic oligophrenia in humans in which the enzyme phenylalanine hydroxylase is absent[5], decreased intelligence is usually observed concomitant with high urinary excretion of phenylpyruvate. While no single test qualifies as an established measure of rat intelligence, the temporal discrimination test offers advantages of efficiency, reliability and relative independence from sensory and motor capacities. In this test, a response of licking a dry dipper was rewarded by the delivery of water on a 2-min. 'fixed interval' schedule[6]. Temporal discrimination was revealed by positively accelerated licking responses within a 2-min. interval as judged from graphic records which were obtained electronically. Eight normal rats and eight rats the diet of which contained 2·5 per cent tyrosine and 2·5 per cent phenylalanine were tested for eight to twelve days under the condition of water deprivation. The frequency of appearance of positive acceleration on days six, seven and eight, expressed as the percentage of the number of intervals showing any responses, averaged 82·9 per cent for normal rats and 46·8 per cent for treated rats. The standard errors of the means were 2·6 and 9·3 respectively. Days on which no responses occurred were excluded from this calculation; their inclusion, however, would increase the difference between groups. Student's *t*-test gave significant differences between groups at less than the 0·01 level. Therefore, animals which had been on a 2·5 per cent L-tyrosine and 2·5 per cent DL-phenylalanine diet had less phenylalanine hydroxylase in the liver, excreted more phenylpyruvate in the urine and showed marked retardation in temporal discrimination learning.

This investigation was supported in part by research grant *CY*-3258 from the National Institutes of Health.

Deoxyribonucleic Acid Content of the Nuclei in the Adrenal Cortex of the White Rat

We have already demonstrated a close relation between the deoxyribonucleic acid content of the nucleus and the functional activity of the cell in the thyroid of the white rat[1]: stimulation inducing an increase, inhibition a decrease of the nuclear deoxyribonucleic acid content.

In the present experiments we have examined whether there is a similar correlation for the adrenal cortex, and whether the localization of a decrease of the nuclear deoxyribonucleic acid content after functional depression by various exogenous steroid hormones supports one of the theories of the histophysiology of the adrenal cortex: the migration theory[2] or the theory of specific functional zoning[3].

Male rats, 7 months old, were used. Observations were made on two series of white rats. In the first the nuclear deoxyribonucleic acid content was assayed in five rats receiving 5 mgm. hydrocortisone daily for two weeks, and in five controls. In the second series the measurements were made respectively on five rats receiving daily doses of 5 mgm. cortisone, in five rats receiving 5 mgm. deoxycortisone acetate, and in five controls. In both series the rats were killed at the same time, their adrenals removed and fixed in a mixture of 40 per cent formol, 96 per cent alcohol and acetic acid (20 : 75 : 5, v/v). After simultaneous fixation and dehydration, and embedding and staining by the Feulgen reaction, the deoxyribonucleic acid content of individual nuclei was measured by the histophotometrical technique of Lison[4].

In every adrenal cortex of the second series 50 nuclei were measured in four different layers: the zona glomerularis, the zona fascicularis externa, the zona fascicularis interna and the zona reticularis. In the first series, however, 100 nuclei were measured in every layer, while no measurements were made in the zona fascicularis interna.

The results of the measurements and of the statistical computations are shown in Tables 1 and 2. The parameters are expressed as the pool of the results of every experimental group. The detailed values for the individual rats will be published elsewhere.

All statistical calculations were performed after logarithmic transformation, as the logarithms of the individual values, and not the values themselves, are normally distributed. The null hypothesis was tested by Student's t-test. We took $P \leq 0{\cdot}01$ as the test of significance: a larger value would be useless since it would be smaller than the experimental error.

Table 1*

		$\bar{x}$	$\log \bar{x}$	s	$s_{\log \bar{x}}$	n

	Zona fascicularis ext.	989	2·995	0·072	0·004	250
	Zona fascicularis int.	941	2·973	0·065	0·004	250
	Zona reticularis	895	2·961	0·071	0·004	250
Cortisone	Zona glomerularis	1,017	3·007	0·083	0·005	250
	Zona fascicularis ext.	931	2·968	0·019	0·001	250
	Zona fascicularis int.	898	2·953	0·064	0·004	250
	Zona reticularis	864	2·936	0·019	0·001	250

* See ref. 4 for symbols, etc.

In the control rats, the same mean values were found in the zona glomerularis and zona fascicularis externa. In the zona fascicularis interna and zona reticularis, however, the mean value of the nuclear deoxyribonucleic acid content was significantly lower ($P < 0{\cdot}001$).

After treatment with hydrocortisone the deoxyribonucleic acid content in the zona glomerularis did not change ($0{\cdot}8 > P > 0{\cdot}7$). In the zona fascicularis externa, however, a significant decrease of the nuclear deoxyribonucleic acid was noticed ($P < 0{\cdot}001$). In the zona reticularis this treatment has no influence on the nuclear deoxyribonucleic acid content ($0{\cdot}2 > P > 0{\cdot}1$). Administration of cortisone had a similar result: no influence on the zona glomerularis ($0{\cdot}2 > P > 0{\cdot}1$), the zona fascicularis interna ($0{\cdot}3 > P > 0{\cdot}2$) and the zona reticularis ($0{\cdot}05 > P > 0{\cdot}02$), but there was a decrease in the deoxyribonucleic acid content in the zona fascicularis externa ($P < 0{\cdot}001$).

The results obtained with deoxycorticosterone-acetate were different. The deoxyribonucleic acid content decreased not only in the zona fascicularis externa ($P < 0{\cdot}001$) but also in the zona glomerularis ($0{\cdot}01 > P > 0{\cdot}001$). That in the zona fascicularis interna ($0{\cdot}05 > P > 0{\cdot}02$) and in the zona reticularis ($0{\cdot}6 > P > 0{\cdot}5$) did not change.

These experiments suggest that there is a relation between nuclear deoxyribonucleic acid content and cell activity in the adrenal cortex. As the localization of the decrease of the deoxyribonucleic acid content depends on the kind of hormone administered, our measurements support the idea of functional zoning of the cortex. Indeed, cortisone and hydrocortisone induce a decrease in the zona fascicularis externa: this observation supports the theory of a specific glucocorticoid function of this zone. Deoxycortisone induces a decrease in both the zona glomerularis and the zona fascicularis externa, which supports the theory of a mineralocorticoid function of the zona glomerularis[5]. Our results, however, suggest that this function is not the exclusive property of the zona glomerularis, but belongs also to the zona fascicularis externa. This conclusion also agrees with recent biochemical investigations, demonstrating the presence of aldosterone in these two layers[6].

These investigations were aided by a grant from the Belgian National Foundation, for Scientific Research. I express also my gratitude to the S.A.

Ciba for providing me with the hormones used in the experiments.

Separation of Mixtures of Œstrogens in Urinary Extracts using Gradient Elution Chromatography

IN the course of studying the metabolism of œstradiol-4-^{14}C in human mammary cancer, a method of separating mixtures of œstrogens was developed. The method consists of gradient elution chromatography on silica gel with progressively increasing concentration of ethyl acetate in benzene. Separation of mixtures of œstrogens on columns impregnated with alkali[1] was considered potentially detrimental to labile œstrogen metabolites. Other schemes, such as chromatography of œstrogen methyl ethers on alumina[3], were likewise considered inadequate to demonstrate subtle œstrogen metabolic differences without risking either partial decomposition or ease of subsequent identification of metabolites. With the system which has been devised, the separation of a synthetic mixture of œstrogens is complete, and excellent recoveries are obtained. The slight variation in retention volumes is presumably due to lack of temperature control. While the capacity of the columns for separating synthetic mixtures has not been determined, microgram amounts of radioactive œstrogens in urinary extracts weighing 250 mgm. have been successfully separated on 2 gm. columns.

The procedure is as follows: the mixture to be separated is applied in benzene solution to 2 gm. of silica gel (Davison Grade 923, 100–200 mesh, washed with methanol, dried at 140° overnight) in a column 15 cm. × 5 mm. internal diameter, prepared as a slurry. When insoluble in benzene, the residue is applied by adsorbing from an acetone (or other suitable solvent) solution on to sufficient silica gel to form a dry, free-pouring powder on removal of solvent. The dried powder is diluted with benzene and redried twice and then carefully applied to a prepared column containing a head of solvent sufficient to avoid formation of air bubbles. Should any bubbles be visible, they may be removed by agitating the extreme top of the prepared column with a stirring rod. A 500-ml. amber bottle (reservoir) containing 300 ml. of ethyl acetate–benzene (1 : 1) is connected to an identical bottle containing 300 ml. of benzene (magnetically stirred) by means of a siphon tube, so that the solvent-levels are kept equalized. A stop-cock along the siphon facilitates filling the tube. A glass tube terminating in a ball joint with an inner seal is used to connect the solvent in the mixing chamber to the column. Since the vessels are of equal diameter, the rate of outflow from the mixing chamber is equal to twice the rate of inflow, and a linear concentration gradient is obtained[2,4,5]. Three-ml. fractions (collected with an automatic fraction collector) are convenient eluate volumes.

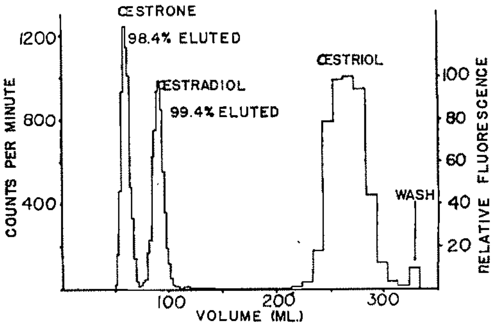

Fig. 1. Separation of a pure synthetic mixture of œstrone, œstradiol and œstriol

The results of a typical separation of a synthetic mixture of œstrone-16-^{14}C, œstradiol-4-^{14}C and œstriol, without urinary extract, are shown in Fig. 1. The first two peaks have been measured radiochemically and the third fluormetrically (relative to the fraction with maximum fluorescence which was designated 100 per cent).

A typical separation which has been obtained with a urinary extract (after enzymatic hydrolysis) from a patient with mammary carcinoma following administration of œstradiol-4-^{14}C, is shown in Fig. 2. The results of paper chromatographic analysis of the material in each radioactivity maximum are shown below each region. This efficient method of separating mixtures of radioactive œstrogens in urinary extracts has also been applied to tissue extracts with comparable success. The applicability of this method to the routine determination of mixtures of non-radioactive œstrogens in various biological media has not been investigated.

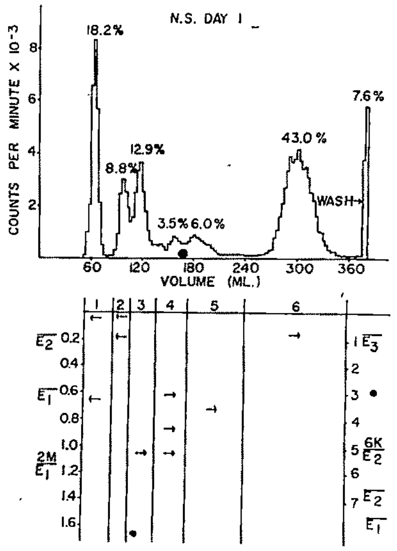

Fig. 2. Separation of urinary extract of patient N.S., day 1, following administration of œstradiol-4-^{14}C. Paper chromatographic mobilities of standards and systems used are indicated to the left and right of each series: left, heptane/methanol; right, benzene/50 per cent aqueous methanol. Direction of arrows at various mobilities designate systems used. Abbreviations are: E_1, œstrone; E_2, œstradiol; E_3, œstriol; 2 $M - E_1$, 2-methoxyœstrone; 6 $K - E_2$, 6-ketœstradiol

'Crossing' Paper Electrophoresis for the Detection of Immune Reactions

Grassmann and Hübner[1] have pointed out the possibility of applying their continuous paper electrophoresis to the detection of loosely bound molecular compounds. The example they gave was a pair of dyes, orange II and methylene blue. These substances were introduced continuously on to a hanging paper at two separate points. They ran down vertically due to gravity and at the same time migrated horizontally towards each other under the influence of the applied electrical field. It was anticipated that the procedure would be applicable not only to the molecular compounds of dyestuffs but also to antigen–antibody complex formation. However, simpler methods have been devised for the antigen–antibody reaction[2–4].

We have succeeded in simplifying and improving the procedure of Grassmann and Hübner merely by making use of ordinary paper electrophoresis. The substances to be tested are applied not as spots but as streaks drawn obliquely to each other (crossed or not crossed). The angle between the streaks remains the same during electrophoresis, but the two lines cross over, since their mobilities differ. (The procedure may thus be called the 'crossing' paper electrophoresis.) The moving force in the direction at right angles to the electric field is not gravity but the difference in the mobilities and the geometry of the lines of the substances. The final result, however, is the same as is obtained by continuous paper electrophoresis.

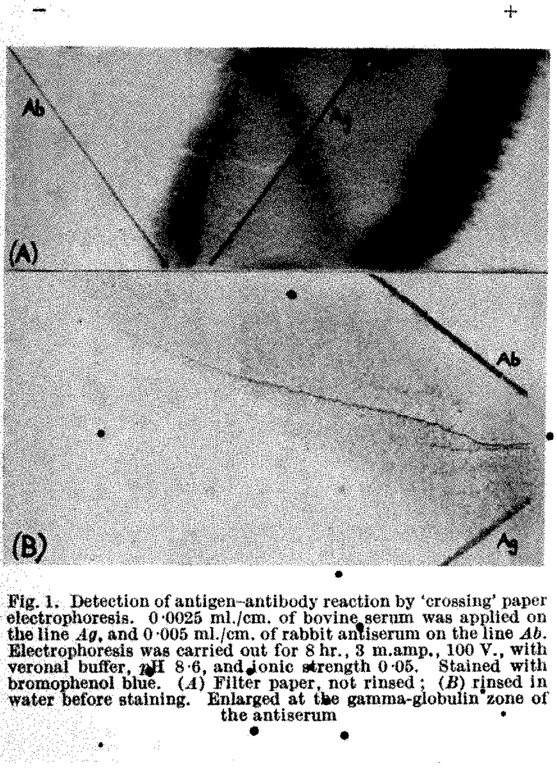

Fig. 1. Detection of antigen–antibody reaction by 'crossing' paper electrophoresis. 0·0025 ml./cm. of bovine serum was applied on the line *Ag*, and 0·005 ml./cm. of rabbit antiserum on the line *Ab*. Electrophoresis was carried out for 8 hr., 3 m.amp., 100 V., with veronal buffer, *p*H 8·6, and ionic strength 0·05. Stained with bromophenol blue. (*A*) Filter paper, not rinsed; (*B*) rinsed in water before staining. Enlarged at the gamma-globulin zone of the antiserum

By this method, the antigen–antibody reaction has been demonstrated on filter paper. As can be seen from Fig. 1, rabbit antiserum (anti-bovine serum) ran ahead and the antigen (bovine serum) ran after. Gamma-globulin of the antiserum was overtaken by the following antigen proteins and crossed over. Thus several lines of precipitates formed gradually alongside the γ-globulin, down to the crossing points of the antigens with it. If the electrophoresis is carried out two-dimensionally, antibody containing γ-globulin was crossed over on a different stretch with each antigenic protein. The ultimate results are almost the same as those obtained by the immunoelectrophoresis of Grabar. The advantages of 'crossing' paper electrophoresis over immunoelectrophoresis are first its simplicity, and second the reduction of material and time needed.

A detailed report and other applications will appear elsewhere.

Mechanism of Oxidative Phosphorylation

THE phenothiazine tranquillizer chlorpromazine has the following actions: (1) It inhibits electron transport between reduced diphosphopyridine nucleotide and cytochrome *c* in appropriate systems; the efficiency of the coupled phosphorylation is not affected. (2) Chlorpromazine is not effective in mitochondria treated with water or in non-phosphorylating reduced diphosphopyridine nucleotide – cytochrome *c* reductase systems. (3) Chlorpromazine prevents the stimulation of respiration in systems deficient in adenosine diphosphate by 2 : 4 dinitrophenol (Table 1). (4) It causes some stimulation of respiration in mitochondrial systems deficient in inorganic phosphate, but not a maximal stimulation (Table 1), without causing any detectable increase in the level of inorganic phosphate. (5) It inhibits powerfully the exchange reaction phosphorus-32 – adenosine triphosphate[1], under conditions in which electron transport cannot be affected (Table 2). (6) It has no effect on succinate – cytochrome *c* reductase in any system.

These findings are interpreted to mean that chlorpromazine inhibits electron transport between reduced diphosphopyridine nucleotide and cytochrome *c* by inhibiting an intermediate in oxidative

Table 1. EFFECT OF CHLORPROMAZINE AND 2 : 4 DINITROPHENOL ON SYSTEMS DEFICIENT IN ADENOSINE DIPHOSPHATE AND PHOSPHATE

Additions	Chlorpromazine (2×10^{-4} *M*)	Oxygen uptake (μ atm.)	
		Deficient in adenosine diphosphate	Deficient in phosphate
Nil	–	4·5	1·1
Nil	+	3·6	2·1
2 : 4 Dinitrophenol ($3 \cdot 3 \times 10^{-5}$ *M*)	–	8·1	6·0
2 : 4 Dinitrophenol ($3 \cdot 3 \times 10^{-5}$ *M*)	+	3·1	3·6

System: ATP, 0·0017 *M*; KCl, 0·025 *M*; $MgSO_4$, 0·0067 *M*; cytochrome *c*, 2×10^{-5} *M*; L-glutamate, 0·01 *M*; inorganic orthophosphate, *p*H 7·2, 0·01 *M* in adenosine diphosphate-deficient system and 0·0017 *M* in phosphate-deficient system. *Tris* buffer, *p*H 7·2 at 0·067*M*. Mitochondria in 0·25*M* sucrose, 1·0 mgm. nitrogen. Final volume, 3·0 ml. Temperature, 38° C. Gas phase, air. Incubation time, 10 min.

Table 2. EFFECT OF CHLORPROMAZINE ON THE EXCHANGE REACTION PHOSPHORUS-32–ADENOSINE TRIPHOSPHATE

	Counts/min. incorporated into adenosine triphosphate	Inhibition (per cent)
Control	3,150	Nil
Chlorpromazine (2×10^{-4} *M*)	1,460	54

System: ATP, 0·0017 *M*; inorganic orthophosphate buffer, *p*H 7·2, 0·0033 *M*; $MgSO_4$, 0·0067 *M*; KCl, 0·025; *tris* buffer, *p*H 7·2, 0·03 *M*; versene, 10^{-3} *M*; phosphorus-32 equivalent to 15,000 counts/min. added. Time of incubation, 15 min. Temperature, 20° C. Specific activity of phosphorus-32, 1,000 counts/min./μmole.

phosphorylation at a point prior to that which is sensitive to 2 : 4 dinitrophenol. We suggest, for example, a modification of the scheme of Chance and Williams[2], as follows:

$$
\begin{array}{ll}
(1) & B + iP \rightleftharpoons B.P \\
(2) & AH_2 + B.P \rightleftharpoons A + BH_2 \sim P \\
(3) & BH_2P + X \rightleftharpoons X \sim P + BH_2 \\
(4) & X \sim P + ADP \rightleftharpoons ATP + X \\
(5) & BH_2 \sim P \rightarrow BH_2 + iP \\
(6) & X \sim P \rightarrow X + iP
\end{array}
$$

In this scheme, AH_2 would represent reduced diphosphopyridine nucleotide and B oxidized flavoprotein. X is the unknown intermediate postulated by Chance. In this scheme chlorpromazine would interfere with reaction (3) and 2 : 4 dinitrophenol with $X \sim P$ of reaction (4). Reaction (5) would be relatively slow, reaction (6) relatively rapid.

These results are being published in full elsewhere[3].

Separation of Glucose-1-Phosphate and Glucose-6-Phosphate by Paper Chromatography

GLUCOSE-1-PHOSPHATE and glucose-6-phosphate are not readily separated by the solvent systems normally used for the analysis of the naturally occurring phosphoric esters on paper chromatograms (for example, propanol–ammonia–water, *t*-butanol–picric acid–water, etc.[1]). Though very similar in structure, the esters differ in that glucose-6-phosphate has two *cis*-hydroxyl groups available for substitution and the addition of boric acid to some of the solvent systems previously described enables glucose-6-phosphate to be differentiated clearly from glucose-1-phosphate[2].

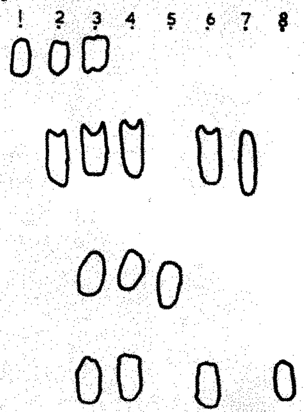

Fig. 1. Chromatogram of phosphoric esters and orthophosphate: (1) fructose-1,6-diphosphate; (2) fructose-1,6-diphosphate + glucose-6-phosphate; (3) fructose-1,6-diphosphate, glucose-6-phosphate, free orthophosphate and glucose-1-phosphate; (4) glucose-6-phosphate, free orthophosphate and glucose-1-phosphate; (5) free orthophosphate; (6) glucose-6-phosphate + glucose-1-phosphate; (7) glucose-6-phosphate; (8) glucose-1-phosphate. Temperature, 20° C.; running time of chromatogram, 48 hr. The paper was equilibrated overnight before the addition of solvent and had been previously washed with acetic acid, distilled water and ammonia (ref. 4)

The addition of boric acid to saturate methyl cellosolve–methyl ethyl ketone–3*N* ammonium hydroxide (7 : 2 : 3 v/v)[3] gives a sharp separation of glucose-6-phosphate from glucose-1-phosphate and from fructose-1,6-diphosphate and inorganic orthophosphate (Fig. 1).

Spatial Summation for Heat-Pain

THE report of an experimental study by Greene[1] on this topic reached me too late for reference to be included in my recent communication[2].

Greene used three methods of stimulation. Two of these—needle-scratch and cold immersion—produced no significant amount of spatial summation. In his third method, of thermal radiation, he used a bank of six 500-W. quartz infra-red lamps so arranged as to produce an even field of radiation over a large area, and found a mean temperature difference in pricking-pain sensation thresholds of 1·1° C. as between an area of 7·8 cm.² and one of 2·5 cm.².

This represented a statistically significant degree of spatial summation, but less than that which I reported for the water-heating method, the difference being probably due to two main variations in the procedures used in the two studies. Thus (1) sizes of area stimulated were different, the smallest area I used being about one-third of that used by Greene; (2) 'threshold' judgments of pain differed in definition and in method of determination.

With reference to this second variation, it is well established that a pricking-sensation threshold, such as that used by Greene, varies little among subjects instructed and practised in distinguishing between that and heat sensations. However, as McKenna[3] points out, this is not strictly a 'pain' threshold. It is therefore probable that these two sets of results demonstrate two different, though closely related, aspects of summative process. Thus, Greene's results may indicate a summation of pricking sensation perhaps initiated in the peripheral events, whereas mine may suggest a summation of pain experience which, by implication, would be of central origin.

Successful Development and Birth of Mice cultivated *in vitro* as Early Embryos

Experimental embryology in mammals is hampered by the comparative inaccessibility of the mammalian embryo. The development of techniques for the cultivation *in vitro* of early mammalian embryos has provided one possible route for experimental interference in the course of embryonic development, through alteration in the conditions of culture and the composition of the culture medium. However, a study of the effects of such experimental interference upon later embryonic development also requires the application of techniques for transplanting early embryos to foster mothers. The first successful attempt to combine the techniques of embryo culture and embryo transplantation was briefly reported by Adams[1]. 16-cell rabbit embryos were incubated for 21½ hr. in Krebs–Ringer bicarbonate containing 2 mgm./ml. bovine plasma albumin, fraction *V* (Armour), during which time cleavage continued at the normal rate. They were then transferred to a recipient female mated 3 days previously to a vasectomized male. One week later there were normal embryos in the uterus of the recipient female, presumably developed from the cultured embryos.

We wish to report an experiment in which viable young were obtained from mouse embryos cultured for 2 days on a synthetic medium during an early stage of embryogenesis, using a culture technique based on that of Whitten[2,3]. As donors, we used immature female mice in which superovulation and mating had been induced by treatment with gonadotrophins[4]. Some of the donors were killed 2½ days after mating; 8–16 cell embryos were recovered from their oviducts and cultured for 2 days at 37° C. in Krebs–Ringer bicarbonate containing 1 mgm./ml. glucose and 1 mgm./ml. crystalline bovine plasma albumin (Armour)[3]. The Krebs–Ringer bicarbonate was prepared from stock solutions on the day that cultures were set up, and gassed with 5 per cent carbon dioxide in air before the glucose and plasma albumin were added. The medium contained no antibiotics or phenol red, but was sterilized by filtration through a sintered glass funnel. The embryos were placed in groups of 4 or 12 into agglutination tubes, each containing 1 ml. of medium. The tubes were closed by silicone bungs after the air above the medium had been replaced by 5 per cent carbon dioxide in air, in order to prevent loss of carbon dioxide and the development of excessive alkalinity. The culture requirements of mouse embryos are more rigorous than those of rabbit embryos, since Adams[1] obtained cleavage without either incorporating glucose in the medium or controlling the *p*H by gassing with carbon dioxide (personal communication), whereas Whitten finds that both procedures are necessary for the development of mouse embryos.

After two days of cultivation, 216/249 (87 per cent) of the mouse embryos had developed into blastocysts. A comparable degree of development takes place *in vivo* in 24 hr., and control blastocysts were therefore recovered from the uteri of the remaining donor animals 3½ days after mating. Control and cultured blastocysts were transferred, following the technique of McLaren and Michie[5], to the uteri of recipient females 2½ days after mating to fertile males. Cultured blastocysts were transferred in the culture medium, and control blastocysts in Pannett and Compton's saline. Of the recipient females which became pregnant, all but two were killed on the sixteenth day of gestation. Since transferred embryos were homozygous for albinism, whereas the recipient females had all been mated to males homozygous for full colour, transferred and native embryos could be distinguished at this stage of development by eye colour. All embryos were individually weighed. The two remaining pregnant females received subcutaneous implants of progesterone to delay parturition and were allowed to proceed to term (19 days), their young being delivered by Cæsarian section.

The results are given in Table 1. The yield of live from cultured embryos (20·4 per cent) proved not to differ significantly from the control yield (21·7 per cent), which was itself similar to that obtained previously by McLaren and Michie[5]. There was a strong indication that the average weight of the cultured embryos was less than that of the control transferred embryos, but on the small numbers available the difference proved not to be significant ($P > 0 \cdot 05$). Even if such a difference exists, it need not indicate any enduring effect of the culture treatment upon subsequent development, since the cultured

Table 1. The Yield of Live Transferred Embryos at the Sixteenth or Nineteenth Day of Gestation in Females which received either Cultured or Control Blastocysts

Mice receiving cultured blastocysts		Mice receiving control blastocysts	
Mouse No.	Yield	Mouse No.	Yield
1	5/9	9	0/9
2	4/11	10	0/11
3	1/9	11	3/12
4	2/11	12	7/17
5	2/16	13	5/20
6	1/12		
7*	0/10		
8*	4/15		
Total	19/93	Total	15/69

Those allowed to proceed to the nineteenth day are marked with an asterisk. The yield is given as the number of live transferred embryos/the number of blastocysts injected into the uterus.

blastocysts may have been at a somewhat earlier stage of development than the controls when transferred.

Only one of the pregnant females allowed to go to term contained cultured embryos. Two of these were successfully fostered on to a newly parturient female. They are at the time of writing four weeks old, and appear in no way affected by their unusual history.

We are indebted to Mr. John Roberts for skilled technical assistance. The work has been made possible by a grant to J. D. B. from the Nuffield Foundation, and a grant to A. M. from the Agricultural Research Council for financial support.

Measurement of Sap Flow by Heat Transfer

It has been assumed by those who have used a pulse of heat as an indicator to measure the rate of flow of sap in trees[1] that the speed of the sap is identical with that of the heat pulse.

That this assumption is not correct can be shown by obtaining the differential equation for heat transfer in an idealized medium consisting of wood substance perforated by many uniformly spaced, parallel straight tubes through which sap flows at a uniform velocity. If the wall thickness between tubes is about 10μ, this medium will approximate the xylem of a conifer. Since a slab of wood substance (diffusivity, $k = 0{\cdot}004$ cm.²/sec.) 10μ thick will heat up to the temperature of its surfaces[2] in 10^{-4} sec., whereas the time associated with the passage of a heat pulse is of the order of minutes in practice, the structure can be treated as a homogeneous mixture from the point of view of heat transfer.

If a fraction, a, of any plane area perpendicular to the x-axis is occupied by sap streams moving with uniform velocity, u, parallel to the x-axis, then the layer of material bounded by the planes x and $(x + \delta x)$ gains heat at a rate per unit area equal to:

$$- au\rho_s c^s \frac{\partial v}{\partial x} \delta x$$

where ρ_s and c_s are the density and specific heat of sap (water), and v is the temperature. On including this term in the derivation of the normal heat conduction equation, one obtains the equation for combined conduction and convection:

$$k\nabla^2 v = \frac{\partial v}{\partial t} + au \frac{\rho_s c_s}{\rho c} \frac{\partial v}{\partial x} \qquad (1)$$

where k, ρ and c refer to the wet wood, that is, to the wood substance together with the stationary and the moving sap.

This equation is identical in form with the equation for pure conduction in a 'medium' moving in the x-direction with velocity[3]:

$$V = au \frac{\rho_s c_s}{\rho c} \qquad (2)$$

That is, the stationary wood and the moving sap together act like a single medium moving at a speed defined by V, the 'heat-pulse velocity'.

Consider a piece of the xylem of *Pinus radiata* with basic density (oven-dry weight/green volume) 0·37 gm./cm.³, and moisture content (relative to oven-dry weight) of 190 per cent. This has $\rho = 1{\cdot}07$ gm./cm.³ and $c = 0{\cdot}77$ cal./gm./° C. The fraction a is not easy to measure, but if we take $a = 0{\cdot}20$ as a reasonable value, equation (2) gives:

sap speed, $u = 4{\cdot}1 \times$ heat-pulse velocity, V

Due to the difficulty of measuring the fraction, a, we have found it more convenient to express the rate of sap flow as 'sap flux', the volume of sap flowing across unit area of the xylem in unit time. We then have:

$$\text{sap flux} = au = \frac{\rho c}{\rho_s c_s} \cdot V = \rho_b\,(m_c + 0{\cdot}33)\,V \qquad (3)$$

where ρ_b is the basic density of the sapwood, m_c is its moisture content, and 0·33 is the specific heat of oven-dry wood.

From the solution of the normal heat conduction equation, for an instantaneous line source of heat along the z-axis[2], one can write the corresponding solution of equation (1):

$$v = \frac{Q}{4\pi kt} \exp\left[-\frac{(x - Vt)^2 + y^2}{4kt}\right] \qquad (4)$$

A sap flow meter based on this equation has been developed in this laboratory. The heater in its simplest form, which is used for limbs up to about 2 in. in diameter, is a piece of 26 standard wire gauge nichrome resistance wire lying along a diameter through which a current up to 40 amp. is passed for 1 or 2 sec. to provide the heat pulse. The temperature is measured at some distance downstream (usually 1·5 cm.) by means of a Philips 83900 3*K*5 thermistor set in the tip of a 21 standard wire gauge hypodermic needle. The quantity of heat in the pulse is chosen to give a maximum rise in temperature at the needle of about 0·3 deg. C.

It has been found in experiments on *Pinus radiata* that, provided the thermistor is deeper than about 0·5 cm. in the sapwood, so that the effect of loss of heat at the surface is avoided, the curve of temperature rise against time agrees closely with that predicted by equation (4). In cases where the agreement is not perfect, usually at comparatively high heat-pulse velocities, very good agreement has been obtained by assuming a uniform spread of heat-pulse velocities over a certain range. Since, however, the best-fitting uniform-speed temperature – time curve corresponds to a speed close to the average of these different speeds, an analysis based on equation (4) is used in routine measurements.

This analysis gives the heat-pulse velocity, V, and the diffusivity, k, in terms of the relative temperature rises at any three times such that one is the average of the other two. This avoids the necessity of calibrating the temperature recorder or the heater. Charts have been constructed for the cases of times in the proportions 1 : 2 : 3 and 1 : 4 : 7, which enable each curve to be analysed in a few minutes.

Experiments have confirmed that dye travels through the xylem of *Pinus radiata* at speeds up to four times greater than the heat-pulse velocity. Equation (3) has also been verified experimentally.

It should be emphasized that this mathematical analysis applies only to such trees as conifers, which have a fine-structured xylem. The case of hardwoods with coarser xylem which cannot be treated as thermally homogeneous has not yet been analysed mathematically, but it is still to be expected that the stationary wood substance will retard the heat pulse to a speed less than that of the sap. The experimental curves in this case are very like those given by the theory above for a spread in heat-pulse velocities ranging down to zero.

Full details of these investigations will be published in *Plant Physiology*.

I gratefully acknowledge the continuous assistance and advice on all botanical aspects of this work of Mr. K. M. Harrow, Plant Diseases Division, Department of Scientific and Industrial Research, Auckland, New Zealand, who originally suggested the project.

Effect of Gibberellin on the Extensibility of the Pea Stem

It has been demonstrated[1-5] that an increase in the extensibility of cell wall is involved in the growth-promoting effect of auxin. Hence it is of interest to see if gibberellin has a similar effect.

Excised pieces of etiolated stem of Alaska pea were soaked in 10 mgm./l. solutions of gibberellin (crystalline mixture of gibberellins by Kyowa Fermentation Co.) and of indole-3-acetic acid, at 25·3° ± 0·2° C. The pieces were subjected, in solution, to a longitudinal tension of 2·5 gm., and the increase in distance between two marks on each piece was measured with a cathetometer.

A representative set of results are illustrated in Fig. 1. The piece treated with indole-3-acetic acid shows temporary extension and contraction respectively at loading and unloading, regular elongation following in both cases. The control piece behaves similarly, but with smaller amplitudes. On the other hand, the piece treated with gibberellin scarcely elongates under load; rather it tends to elongate when unloaded.

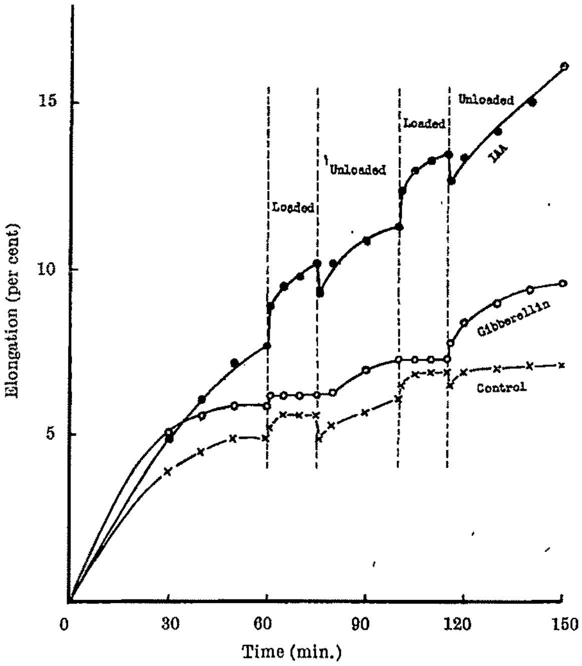

Fig. 1. Changes, due to loading and unloading, of the distance between two marks on a stem piece soaked in water and in solutions of indole-3-acetic acid and of gibberellin

Tagawa and Bonner's method[5] was modified so that the stem piece was bent while it was held in the solution. The stem piece was soaked for 2 hr. in a solution of indole-3-acetic acid (10 mgm./l.) or of gibberellin (20 mgm./l.) or in distilled water, and then a tangential force was applied to one end with a weight. The piece bent as *A B C C′* (Fig. 2). The degree of bending varied considerably from piece to piece. However, a smaller variance was obtained by taking the ratio of the angle increment in the first minute (*A*—*B*) to that in a longer period (for example, *A*—*C′*). This ratio can be called the 'relative incipient bending'. When the force was removed at *C*, the piece unbent to *C D E*, due to its elasticity. The remaining angle, that is *A*—*D* or *A*—*E*, represents the plasticity.

As shown in Table 1, the relative incipient bending is enhanced by treatment with indole-3-acetic acid and is lowered by treatment with gibberellin, as compared with the control. These results show that indole-3-acetic acid makes the stem piece more yielding to an extending force while gibberellin makes it less so. Similarly, the plasticity is increased by indole-3-acetic acid and decreased by gibberellin.

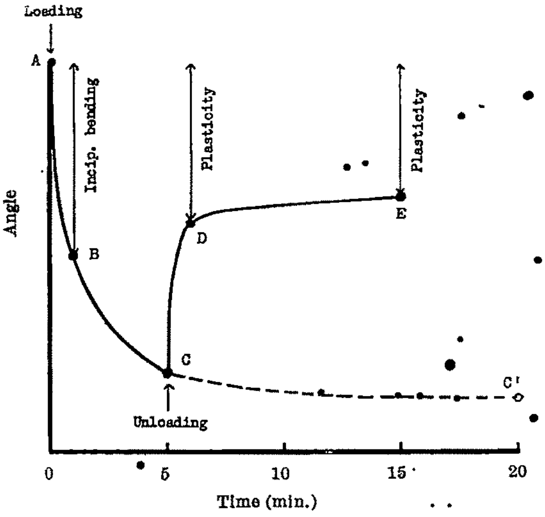

Fig. 2. Diagrammatic representation of process of bending and unbending

Table 1. Relative Incipient Bending and Plasticity of the Pea Stem Piece pretreated with Indole-3-Acetic Acid, Gibberellin or Water for 2 hr.

For *A*, *B*, *C*, *C'*, *D* and *E*, see Fig. 2. Heavy load, 686 mgm.; light load, 456 mgm. Average of five samples and probable error

	Incipient bending $\frac{B-A}{C'-A}$ (per cent)		Plasticity (after heavy loading) (per cent)	
	Heavy load	Light load	$\frac{D-A}{C-A}$	$\frac{E-A}{C-A}$
Indole-3-acetic acid (10 mgm./l.)	—*	67·8 ± 2·5	60·7 ± 1·8	54·7 ± 2·7
Gibberellin (20 mgm./l.)	56·4 ± 3·9	49·3 ± 5·1	51·9 ± 1·3	44·7 ± 1·7
Control	66·6 ± 4·6	56·7 ± 5·4	54·8 ± 2·1	50·9 ± 3·1

* Too much bending occurred within 20 min.

It is therefore suggested that gibberellin has an effect opposite to that of auxin on the extensibility and particularly the plasticity of the stem. Details, together with further studies, will appear elsewhere.

Effect of Gibberellin on Sunflower Tissue Culture

Recently Nickell[1] reported the effect of gibberellin on several plant tissues grown *in vitro*. The results were generally non-specific. Sunflower petiole crown-gall tissue growth was inhibited rather drastically by 10 p.p.m. of gibberellin, whereas tobacco and sweet clover were somewhat enhanced by it. Schroeder and Spector[2] showed marked increased effect of gibberellin on growth of mature citron explants in the presence of indoleacetic acid, but very limited growth in its absence. The accelerating influence or interaction of indoleacetic acid on other growth factors (for example, kinetin[3]) and gibberellin[4 5] has been a well-observed fact in many experiments and observations relating to correlation of growth factors[6].

In the experiments reported here tissue of sunflower origin[7] was used. The method was similar to that used in former experiments with this tissue[8]. The gibberellin was added to the media containing indoleacetic acid or lacking it to make final concentrations of 0·001 to 1·0 p.p.m. for habituated tissue (H_h), and 0·2 to 200 p.p.m. for tumour tissue (*Pv*). The media (*p*H 6·0) were autoclaved at 20 pounds pressure for 15 minutes. There were 5 replicates at each concentration of gibberellin. The weights were taken after 8 weeks growth.

The results are strongly in agreement with Nickell, indicating a non-specific influence. Tumour tissue appears to be generally inhibited by the addition of gibberellin. There is no significant increase in any of the concentrations. Tumour tissue, as might be expected[8], grows better on medium lacking indoleacetic acid. Habituated tissue shows no response to gibberellin at the relatively low levels used.

Table 1. Growth of Sunflower Tumour Tissue on Gibberellin Cultures 8 weeks old (10–5–58 to 3–7–58). Wet weight (gm.)

Gibberellin (p.p.m.)	GBA* − indoleacetic acid	GBA* + indoleacetic acid
0	1·67	0·62
0·2	0·98	0·31
2·0	0·76	0·51
20·0	0·86	0·79
200·0	0·64	0·39

* GBA consists of Gautheret (½ Knop) medium, Berthelot minor elements and addendum of vitamins, amino-acids, adenine sulphate.

Table 2. Effect of Gibberellin on Habituated Tissue of Sunflower

Cultures 8 weeks old (21–12–57 to 13–2–58). Wet weight (gm.)

Gibberellin (p.p.m.)	GBA + indoleacetic acid
0	0·35
0·001	0·28
0·01	0·32
0·1	0·36
1·0	0·36

These results are similar to those recorded for these same strains of tissues (plus the normal strain of sunflower callus tissue, H_n) grown on the basal media, GBA (see Table 1), with and without indoleacetic acid, in the presence of kinetin at 0·01, 0·1 and 1·0 p.p.m.[9]. In this experiment, also, H_h and H_n showed very little deviation from the controls, especially the normal callus, H_n.

The results of Nickell and those reported here seem to suggest a general principle in plant tissue culture, of the callus type, namely, that when tissue cultures which have been grown for many passages on specific media are subjected to certain new factors, such as gibberellin and kinetin, they no longer adapt or respond as rapidly as do freshly cut explants such as carrots used for certain chemical assays[10] or the citron tissues of Schroeder and Spector. These slices are more like the original tissues *in vivo* where gibberellin especially is most demonstrative in its effects on growth.

I wish to thank Chas. Pfizer and Co., Inc., for supplying the gibberellin.

Synthesis of Blood Protein by the Fat Body in the Silkworm, *Bombyx mori* L.

The concentration of protein in the blood of insects changes remarkably in the course of metamorphosis[1]. I have shown that the concentration of blood protein increases after the middle period of the last larval instar[2] in the silkworm. It is not yet clear, however, what organ is concerned in the synthesis of blood protein in larval stage, although there are reports by Sissakian and Kuvaeva[3] that

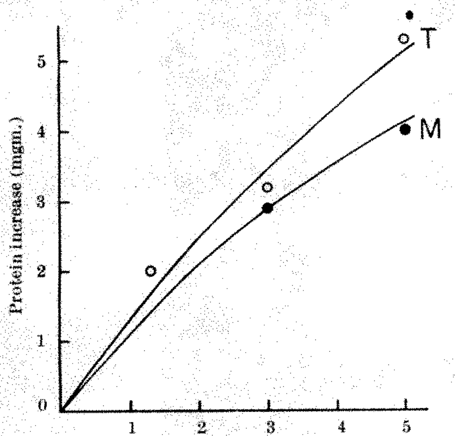

Fig. 1. Increase in the amount of protein in the tissue (*T*) and in the medium (*M*) during *in vitro* protein synthesis by the fat body. Initial amount of protein in the tissue, 34·2 mgm.

blood itself synthesizes the protein in the pupal period of the silkworm. It was demonstrated that the content of protein in the fat body per individual remained almost constant after the middle period in the last larval instar, meanwhile activity to synthesize protein by the tissue was rather high in the same period[4,5]. In order to elucidate the fate of the protein, the following experiments were carried out.

In the first experiment, net synthesis and secretion of protein by the fat body was demonstrated. The fat body of the silkworm, 500 mgm., was incubated in a medium consisting of 1·6 ml. of saline solution (sodium chloride 0·4, potassium chloride 0·05, calcium chloride 0·02, magnesium sulphate 0·01 per cent and phosphate buffer $M/150$, pH 7·0), 0·4 ml. of boiled extract of blood, 20 mgm. of casein acid hydrolysate as amino-acid source and 10 µmoles of adenosine triphosphate, for 1–5 hours at 30° C. After incubation, medium and tissue were separated by filtering through paper and determination of protein content was carried out on both the fractions. The result shown in Fig. 1 indicates that protein content in both fractions increases. The increase was completely inhibited by addition of 2 : 4-dinitrophenol. No disintegration of the tissue seems to occur during the tissue culture in such a short time as five hours. Therefore, it is highly probable that the increase in protein content in both tissue and medium shows the synthesis of protein in the tissue and the secretion thereof into the medium.

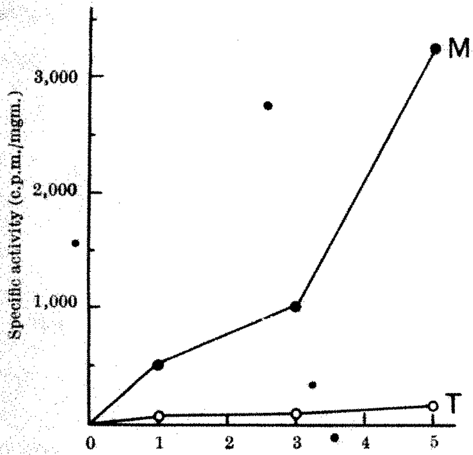

Fig. 2. Increase of the specific activity of protein in the tissue (*T*) and in the medium (*M*) during the *in vitro* incorporation of labelled amino-acids by the fat body

In the second experiment, the incorporation of amino-acids labelled with carbon-14 into protein was investigated to confirm the synthesis and the secretion of protein by the tissue. The reaction was carried out in a medium consisting of 0·8 ml. of saline solution (the same constituent as preceding experiment except that sodium chloride was 0·7 per cent), 0·2 ml. of boiled extract of blood, 1 per cent glucose, 5 µmoles of adenosine triphosphate, 0·5 µc. of labelled amino-acid mixture (isolated from *Euglena* cultured in a carbon-14-dioxide atmosphere), and the 200 mgm. fat body at 33° C. After incubation, medium and tissue were separated as above and fractionated to obtain the protein fraction. Radioactivity in each of the protein fractions was measured by a gas-flow counter and the specific activity calculated (c.p.m./mgm. protein). The radioactivity of substances adsorbed on to the protein was subtracted from the experimental value. As shown in Fig. 2, after five hours incubation the specific activity of the medium protein reaches a level far higher than that of the tissue protein. If the medium protein consists of a part of tissue protein broken down during the incubation, the specific activity of the medium protein should be the same as, or even lower than, that of the tissue protein. This result indicates strongly that the fat body synthesizes and secretes a certain kind of protein.

In the third experiment, the nature of the protein secreted by the fat body was investigated by paper electrophoresis. This was carried out on a strip of Tōyō filter-paper No. 51 for 15 hours at room temperature with a current of 0·5 m.amp/cm. at 200–100 V. using veronal buffer (0·05 M, pH 8·6). The result is shown in Fig. 3. The mobilities of the main

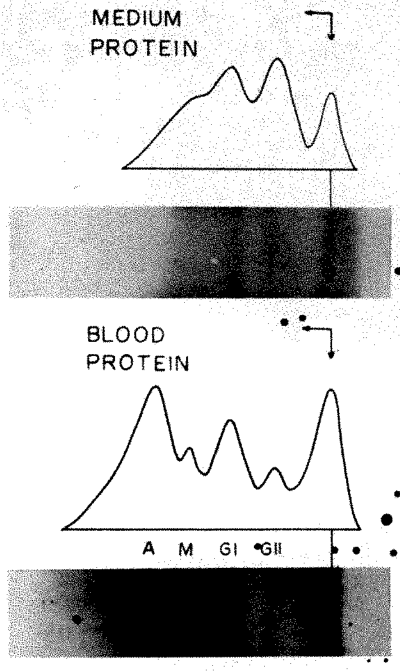

Fig. 3. Paper electrophoretic patterns of medium protein after 5 hr. of protein synthesis *in vitro* by the fat body, and of blood protein at the eighth day of the fifth larval instar

components of the medium protein were similar to those of the globulin components of blood protein. It is generally accepted that blood protein of the silkworm consists of three main components and one less conspicuous component *M*. The former are albumin (*A*) and two globulins (*G* I and *G* II), the *M* component appears only in females at the prepupal stage[6,7]. Furthermore, in blood, the ratio of the two globulin components to the total protein content increases after the middle period of the fifth instar[7].

The rate of increase in quantity of blood protein was about 13 mgm. per individual per day during the later half of the last larval instar. In the first experiment, the increase of protein in the medium after 5 hours *in vitro* corresponds to about 12 per cent of the initial amount of tissue protein. In the silkworm, the amount of protein in the fat body remains almost constant at about 20 mgm. per individual during the second half of the last larval period[4]. Therefore, the quantity of protein secreted by the fat body can be calculated as about 12 mgm. per individual per day, about the same as the increase in blood protein *in vivo*.

From these facts, I propose that the fat body of the silkworm synthesizes globulins and secretes them into the blood circulation in a larval stage, at least in the fifth larval instar.

The molecular weight of the globulin components of blood protein is, however, large according to Oda[8], and the mechanism of secretion of these components of high molecular weight still remains unknown.

I wish to thank Mr. Hiro-o Takeshita and Miss Tomoko Koyasako for technical assistance in this work.

Effects of Rust Infection on the Carbohydrate Metabolism of Wheat Seedlings

In the course of studies on the nature of resistance of plants to disease, experiments were performed to determine the effect of stem rust (*Puccinia graminis* Pers. f. sp. *tritici* Erikss. and Henn., race 34) infection on the distribution of the carbon-14 of photosynthetically fixed carbon-14 dioxide among the sugars in the wheat varieties Gabo 54 and Little Club. These varieties are resistant (reaction type 1) and susceptible (reaction type 4), respectively, to race 34 of the pathogen.

Seedlings, grown in nutrient solution, were inoculated at the two-leaf stage on both their leaves, while comparable seedlings remained uninoculated to serve as controls. Seven days later, both the inoculated and then diseased seedlings, and the uninoculated healthy controls were placed in an atmosphere enriched with carbon-14 dioxide, in the light, for 1 hr. Immediately afterwards, the first two leaves were extracted with 80 per cent boiling ethanol. They were further extracted with 30 per cent boiling ethanol and finally, in a Soxhlet extractor, with 90 per cent ethanol. The three fractions thus obtained were combined, and the alcohol was removed by vacuum distillation, the chlorophylls by extraction with benzene, and the ionic substances by treatments with ion-exchange resins[1]. The resulting purified sugar solution was analysed by 1-dimensional paper chromatography, using *n*-butanol/acetic acid/water (4 : 1 : 5 v/v/v) as the solvent and Whatman No. 1 filter paper. The chromatograms were irrigated and dried three times before development. The position of the radioactive components on the chromatogram was detected by autoradiography. Sugars were identified by 2-dimensional co-chromatography and by their colour reactions to specific reagents[2].

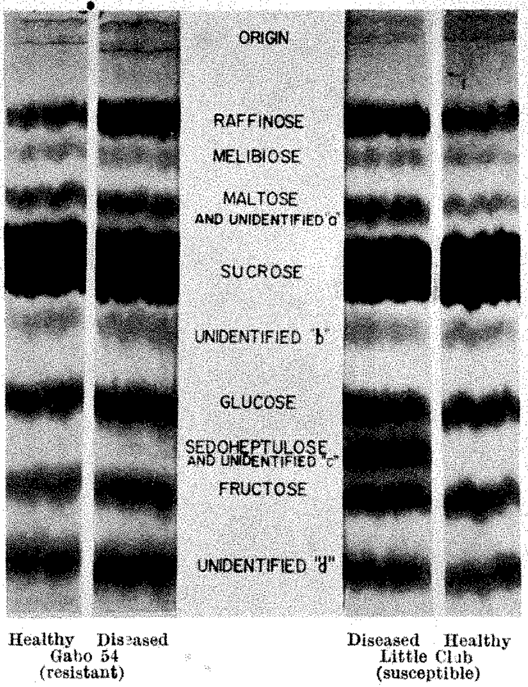

Fig. 1. Autoradiogram of chromatograms of the sugars in healthy and stem-rust infected (diseased) wheat leaves, grown in an atmosphere containing carbon-14 dioxide

At least nine radioactive bands were detected on the chromatograms in all cases (see Fig. 1). The sugars in six of these bands were identified as raffinose, melibiose, maltose mixed with an unidentified compound, sucrose, glucose and fructose. The three other bands, which included the origin, contained unidentified compounds. One additional band was detected on the chromatograms of the extract of diseased leaves of the susceptible variety, Little Club. This band split into two when the paper was irrigated for a longer period of time than that used in preparing the chromatograms of the autoradiogram of Fig. 1. The compound in one of these two bands was sedoheptulose, that in the other band was not identified.

All the sugars that were identified in this work had previously been reported to occur in wheat leaves[3,4], except maltose and sedoheptulose. In view of the fact that infection was light, and as a consequence mycelium and spore production was small, it can be assumed that, except for amounts probably too small to be detected by the method used, all the radioactive sugars detected in leaves occurred in the host cells.

The accumulation of carbon-14 in sedoheptulose in rusted leaves of the susceptible plants was the most striking metabolic alteration caused by infection. However, infection affected also the amount of carbon-14 fixed in the other sugars. In general, the relative radioactivities of the sugars were increased by infection. Sucrose was an exception, its radioactivity being decreased. The relative radioactivities of the sugars as modified by infection, suggestions respecting the biochemical mechanisms responsible for the pathological accumulation of sedoheptulose and alterations in the distribution of carbon-14 among the sugars, and comments on the significance of these results in relation to resistance and susceptibility to rust, will be published elsewhere.

Induced Resistance of Mice to Infection with *Brucella abortus* 2308 through Vaccination with *BCG*

NON-SPECIFIC factors affecting the immunological state of the host have recently been the subject of many investigations. Some of these were concerned with the increase in resistance to tuberculosis[1-4]. The enhancement of resistance of mice to *B. abortus* infection following vaccination with *BCG* appears not to have been reported so far.

Swiss albino mice weighing 15–18 gm. were used. All immunization and challenge doses were administered intra-abdominally. A group of mice were injected with 0·4 mgm. of *BCG* cells taken from a three-week culture on Petragnani's medium. Another group were injected with 2 mgm. of heat-killed (1 hr. at 70° C.) *BCG* taken from the same medium. Groups of five mice from the animals immunized with living *BCG* were challenged at two, three, four and six weeks after immunization with 0·2 ml. of a suspension of the virulent *B. abortus* 2308, containing 30,000 cells. Groups of five mice from the animals immunized with killed *BCG* were similarly challenged at two and four weeks after immunization. Control groups of five mice were also injected with *Brucellae* and included in the experiment. Seven days after challenge all mice were killed with ether and their spleens removed aseptically. The five spleens of each group were homogenized and suspended in 25 ml. tripticase soy broth. 0·2 ml. of 1 : 10 and 1 : 100 dilutions of this suspension were spread on tripticase soy agar plates. The colonies were counted after four days incubation at 37° C. Table 1 shows the results of this experiment.

Table 2. RADIOACTIVITY (C.P.M.) IN THE SPLEENS OF MICE VACCINATED WITH LIVING OR KILLED *BCG* AND CHALLENGED WITH RADIOIODINATED *B. abortus*

Mice No.	Counts per min. in spleens of

8				5,535
Mean counting rate	1,818	4,168	1,785	4,785

* Interval between vaccination and challenge, 34 days. † 19 days.

The number of *Brucella* cells in the spleens of normal mice was 25–300 times larger than that in the spleens of mice vaccinated with living *BCG*. The immunizing effect of killed *BCG* was less marked. However, the spleen counts of mice vaccinated with killed *BCG* were 5–36 times less than those of non-vaccinated controls. Such differences can be regarded as an indication of a marked immune state.

The immunizing effect of *BCG* was confirmed with an additional technique. It was recently reported that following intra-abdominal inoculation, the distribution of killed, radioiodinated *Brucellae* in the organs of specifically immunized mice was strikingly different from that in the organs of normal animals[5]. The spleens of immune mice collected a lower amount of radioactivity than the corresponding organs of the normal animals. Table 2 shows that a similar distribution of *Brucellae* could be induced when *BCG* was used for immunization. Groups of mice were vaccinated with 0·1 ml. of a ten-day 'Tween' albumin culture of *BCG* or with 2 mgm. of heat-killed *BCG* grown on Petragnani's medium. These mice and normal controls were injected intra-abdominally with 0·3 mgm. (~ 100,000 counts per min.) radioiodinated

Table 1. MULTIPLICATION OF *Brucella abortus* 2308 IN THE SPLEENS OF MICE VACCINATED WITH *M. tuberculosis BCG*, 2, 3, 4 and 6 WEEKS PRIOR TO CHALLENGE

BCG cells used for immunization	No. of cells recovered from spleens and protection indices*

Antituberculous Factors of Milk

Milk and milk-whey have been found to contain one or more anti-tuberculous agents[1]. The administration of milk, milk-whey or the dialysate of the latter which passed through a 'Cellophane' membrane, inhibited the development of experimental tuberculosis in the mouse. The question arises whether an inhibitory influence on the mycobacterium is responsible for this effect. If so, the material obtained from milk should be effective *in vitro*. *In vitro* experiments with milk, milk-whey and its dialysate were therefore performed.

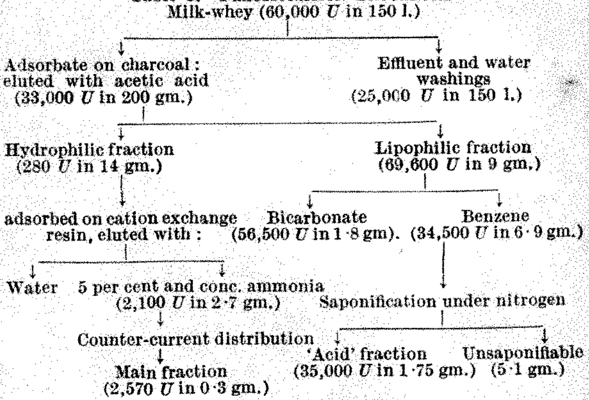
In these tests the material was diluted with Kirchner's medium before Seitz-filtration. When milk, milk-whey or milk-whey dialysate were concentrated *in vacuo* and diluted with the medium to reconstitute their original concentration in the milk, total growth inhibition of *Mycobacterium tuberculosis* strain *H*37*Rv* occurred. No extraneous antiseptics or antibiotics were used in feeding the cattle or in milking or dairying. Inhibitory activity was also found in goats and human milk.

Further experiments, which are summarized in this communication, were attempted in order to concentrate and characterize the active principle from cow's milk.

As a first step, milk-whey was adsorbed on charcoal ('Karborafin', Hrušovské chemické závody). This retained about half the activity, which could be desorbed with glacial acetic acid after a preliminary wash with water. The dry residue of the acetic eluate represented less than 10 per cent of the dry weight of the whey and contained, besides other substances, much lactose, lactic acid and peptides. On fractional precipitation the activity remained largely in the liquid phase up to a concentration of 90 per cent acetone, most of the lactose and peptides of higher molecular weight being precipitated.

Distribution between an acid-aqueous phase and an organic one, such as chloroform, made it possible to separate the inhibiting activity into lipophilic and hydrophilic factors. The lipophilic fraction contains most of the activity (Table 1). When distributed between benzene and an aqueous bicarbonate solution, the activity in the lipophilic fraction separates into two fractions, most of the activity passes into the bicarbonate layer, but some remains in the benzene and cannot even be extracted with 1 *N* sodium hydroxide. The activity which passed into bicarbonate can be re-extracted in an organic solvent after acidification, and thus behaves like an organic acid. Fatty acids of medium chain-length, especially lauric acid, were identified and estimated by reversed-phase paper chromatography[2]. Calculations and comparative inhibition tests showed that the saturated straight-chain fatty acids of medium chain-length, although active against *Mycobacterium tuberculosis*[3], cannot be responsible for more than 1–5 per cent of the activity of this fraction.

Table 1. Fractionation Procedure



Milk-whey (60,000 U in 150 l.)
Adsorbate on charcoal: eluted with acetic acid (33,000 U in 200 gm.)
Effluent and water washings (25,000 U in 150 l.)
Hydrophilic fraction (280 U in 14 gm.)
Lipophilic fraction (69,600 U in 9 gm.)
adsorbed on cation exchange resin, eluted with:
Bicarbonate (56,500 U in 1·8 gm).
Benzene (34,500 U in 6·9 gm.)
Water
5 per cent and conc. ammonia (2,100 U in 2·7 gm.)
Saponification under nitrogen
Counter-current distribution
'Acid' fraction (35,000 U in 1·75 gm.)
Unsaponifiable (5·1 gm.)
Main fraction (2,570 U in 0·3 gm.)

The 'neutral' (more lipophilic) fraction can be saponified by alkali, and after removing the unsaponifiable material an active fraction can be extracted into bicarbonate from benzene. It also contains fatty acids of medium chain-length, but these are no more active than the fatty acids of the other acid fraction.

Most of the growth-promoting substances are concentrated in the hydrophilic fraction, together with the inhibitory principle, and they thus partially mask its activity. Further purification therefore is accompanied by a rise not only of specific activity but also of overall activity (Table 1). Owing to its cationic character the active principle can be retained on a cation exchange column (*FN*, Stalinovy závody, containing sulphonic groups). It is not washed out by water but 5 per cent ammonia begins to elute it. A considerable rise of activity occurs. Further purification is obtained using a counter-current distribution between *n*-butanol and water acidified to *p*H 3.

This hydrophilic factor is not retained on anion exchange resins and therefore differs from the urinary principle described by Björnesjö[4]. The protein lactenin, isolated by Jones[5], can likewise be excluded, but similarity to the basic tissue peptides studied by Dubos[6] and Bloom[7] is possible.

It can thus be concluded that at least three factors inhibitory to the growth of *M. tuberculosis* *H*37*Rv* in a liquid medium are contained in cow's milk-whey. The elucidation of a possible relationship between the substances active *in vitro* and the protective activity of milk-whey in experimental mouse tuberculosis awaits further study.

Concentrates of the hydrophilic factor (1,000 *U*/gm.) (one *U* is defined as the amount per ml. cultivation medium that causes a 50 per cent inhibition of growth in *M. tuberculosis* *H*37*RV*) and of the lipophilic factor (5,000 *U*/gm.) were tested against the following bacteria: *Streptococcus haemolyticus* β; *Staphylococcus pyogenes aureus* (Oxford); *Escherichia coli*; *Pseudomonas aeruginosa*; and *Bacillus subtilis*.

No inhibition was observed up to a concentration of 10 mgm./ml. test solution in plate tests and up to the concentration of 1 mgm./ml. in liquid cultures, thus demonstrating a high antibacterial specificity. The inhibitory activity of the unfractionated concentrate against *Mycobacterium tuberculosis H37Rv* was not removed by the addition of ox serum instead of tween-80 to the liquid medium. (We are indebted to Dr. V. Bydžovský and Mrs. A. Čížková for these results.)

The concentrate was also active against *Mycobacterium tuberculosis* (*H37Rv* and several first cultures) in solid medium according to Löwenstein, but inactive against the *BCG* strain, *Mycobacterium phlei* and *M. smegmatis*. (These tests were performed by Dr. Šula and Dr. Švachulová in the Research Institute for Tuberculosis, Prague.)

Effect of Total Body Irradiation on Capillary Permeability

It seems to be generally accepted that increased permeability of the capillary wall is one of the basic changes caused by exposure to massive X-irradiation. It must be emphasized, however, that the proofs for this supposition are very inconclusive. Tendency to bleeding and diffuse hæmorrhages may be produced not by increased permeability, but (besides the accompanying hæmatologic disorders) by an increase of capillary fragility, that is of susceptibility to injuries of the capillary wall.

The permeability of capillaries can only be tested by substances passing through their walls by filtration or diffusion. An increase of permeability is indicated by a more rapid passage of these substances, especially of plasma proteins and of colloids in general. Systematic studies on the passage of colloids through the capillary walls in irradiated animals are few. The decrease of plasma concentration depends, however, not only on the transcapillary migration of the colloid molecules but also on the return of the labelled protein by way of the lymphatic channels.

The purpose of the present studies was therefore to investigate the disappearance of labelled plasma proteins from the circulation as well as their transport through the lymphatics after massive total body X-irradiation.

All investigations were carried out on normal mongrel dogs of 8·5–19·5 kgm. body-weight. Animals were subjected to total body X-irradiation ranging from 500 to 700 r., delivered from a Siemens–Stabilivolt therapy unit at dose-rates about 17·6 r./min., other radiation factors being 180 kV., 15 m.amp., 1 mm. copper, and 85 cm. target-skin distance. On the third to the twenty-fifth day after irradiation the dogs were anæsthetized with chloralose (0·1 gm./kgm.) and a polyethylene tube was inserted into the thoracic duct at its junction with the great veins. 1–6 ml. of iodinated human serum albumin (iodine-131 activity 2–3 μc.) and 2–3 ml. of a 0·5 per cent Evans-blue solution were injected intravenously and plasma and lymph samples collected. In control experiments the same procedure was performed in 9 normal dogs.

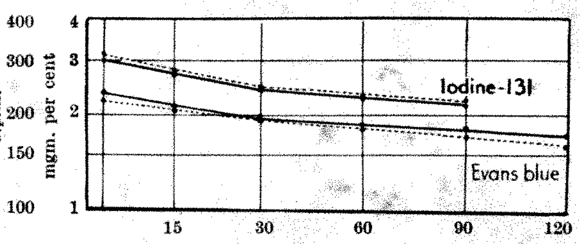

Fig. 1. Concentration in blood plasma of injected Evans-blue and albumin labelled with iodine-131 in normal and in irradiated dogs with thoracic duct fistula. ———, Normal dogs; – – – –, irradiated animals

Besides the well-known decline in erythrocyte count and an extreme fall of the leucocyte count, a slight diminution of plasma protein concentration (1·1 gm. per cent; standard deviation, $s = 1{\cdot}1$; $P = 5$ per cent) was detected. In contrast to the results of Ferrell, Turner and Overman[1] a decrease of circulating plasma volume ($-15{\cdot}1$ per cent; $s = 8{\cdot}7$) occurred. This decrease was, however, roughly parallel with the loss of body-weight (-16 per cent; $s = 7{\cdot}7$). As regards the disappearance of the tagged protein and of Evans-blue injected, there was no significant difference between the irradiated animals and the controls (Fig. 1). The fraction of albumin labelled with iodine-131 and of Evans-blue leaving the circulation in one minute (k) calculated after Wasserman and Mayerson[2] was practically identical in both groups of animals. (In the first 30 minutes the value of k was 0·00669; $s = 0{\cdot}00180$

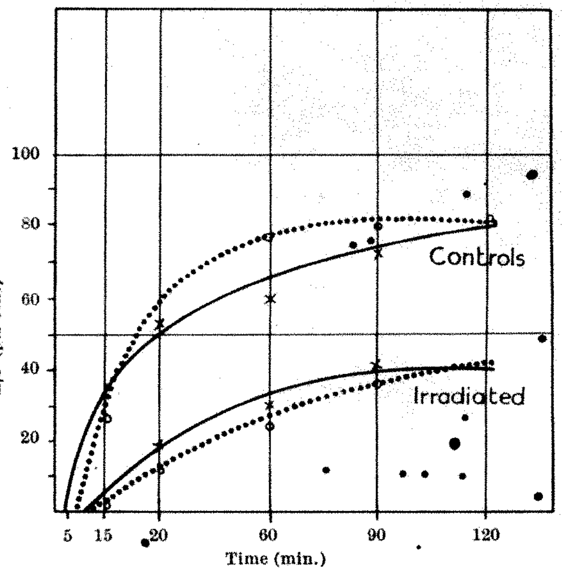

Fig. 2. The effect of irradiation on the equilibration between plasma and lymph of injected labelled protein. L/P, Concentration in lymph/concentration in plasma as percentage. ......, Evans-blue; ———, albumin labelled with iodine-131

for Evans-blue; 0·00775, s = 0·00433 for albumin labelled with iodine-131 in the irradiated; and 0·00699, s = 0·433; 0·653; s = 0·00302 respectively in the normal dogs. Between 30 and 90 minutes after injection the respective values were 0·00191, s = 0·00072; and 0·00245, s = 0·00154 in the irradiated; 0·00223, s = 0·00138; and 0·00226, s = 0·00077 in the normal dogs for Evans-blue with respect to albumin labelled with iodine-131; the differences were not significant.) The concentration of Evans-blue and labelled albumin in the lymph in the irradiated dogs definitely rose more slowly than in the controls, and 90–120 minutes after the injection attained only 42·3 (Evans-blue) and 39·9 (labelled albumin) per cent of the plasma concentration, whereas in the controls the relative concentrations were 82·1 and 78·8 per cent (Fig. 2). Due also to a decrease in flow of lymph, the back-transport of the labelled protein from the tissue spaces to the circulation was greatly reduced. During the first hour the leakage in the normal dogs amounted to 26·1 (s = 4·6) per cent of injected Evans-blue and 18·7 per cent (s = 5·5) of albumin labelled with iodine-131. In the irradiated animals the respective values were 21·1 (s = 3·1) per cent; the differences were not significant. On the other hand, during the same period, the thoracic duct in the normal animals transported 4·96 (s = 2·66) per cent of injected Evans-blue and 3·93 (s = 1·66) per cent of labelled albumin, whereas in the irradiated animals the lymphatic returns were respectively only 0·46 (s = 0·30) and 0·39 (s = 0·24) per cent of the injected amount.

In 4 out of 7 irradiated animals the lymph contained a considerable amount of erythrocytes (49,000–625,000 per mm.^{3}).

In our experiments on irradiated animals no increase in transport of colloidal molecules through the capillary walls could be detected. The return of the extravasated protein molecules by way of the lymphatic channels was, however, greatly reduced. The appearance of hæmorrhagic manifestations as well as of red blood cells in the lymph detected by Furth *et al.*[3] and observed also by us indicates marked capillary damage, but, as we have already pointed out, this phenomenon has no direct connexion with the passage of colloidal molecules. In normal circumstances plasma proteins leave the circulation at a constant rate, passing across pores of molecular dimensions. As colloidal molecules cannot re-enter the capillaries the magnitude of this transcapillary exchange can be estimated by investigating the lymphatic transport. Porker, Chaikoff and Reinhardt[4] established that in the dog approximately half of the total plasma protein traverses the thoracic duct per day. In view of the large transcapillary exchange of protein under normal circumstances, and the comparatively large total pore surface area, the leakage of protein through the openings in the damaged capillary wall may presumably be neglected.

Our results suggest that the return of extravasated protein through the lymphatic channels is greatly reduced in irradiated animals.

A decreased lymphatic transport of tagged protein must result (without any acceleration of passage through the capillary walls) in a quicker decrease of its plasma concentration, as observed by Wish *et al.*[5]. In our investigations, however, the main lymphatic trunk being divided, this phenomenon could not be detected. As protein leaving the circulation can return by way of the lymphatic channels only, delayed lymphatic transport leads to considerable loss of plasma protein.

Origin and Connexions of the Central Nutrient Mass in *Lumbricus* Spermatogenesis

Examined by electron microscopy, the central nutrient mass around which spermatogonia up to spermatozoa are attached is seen to be non-nucleated and to contain mitochondria (*M*, Fig. 1) and various types of nutrient spheres and vacuoles. All spermatic cells are connected to this central mass by bridges (*J*, Fig. 1) which become much attenuated as the spermatic cells develop. The central nutrient mass is developed in the middle of the spermatogonial syncytium during early growth stages of the spermatocytes, and through these bridges all cells draw upon this store equally for their development into spermatozoa, thus being kept in step.

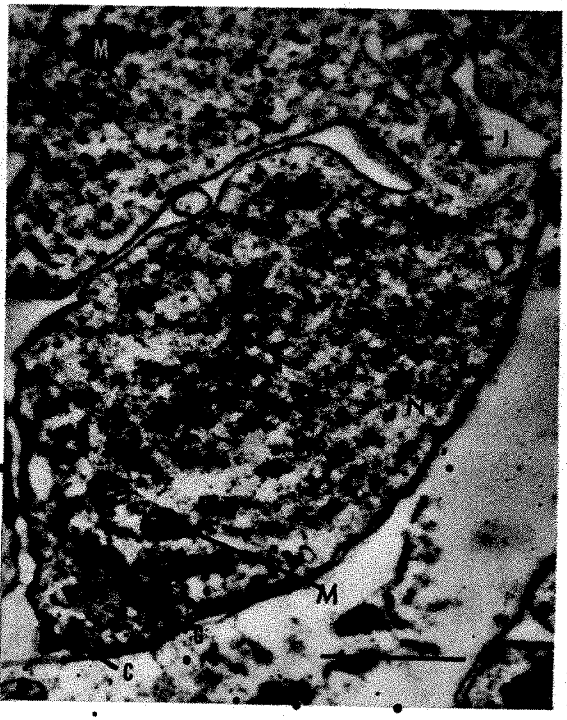

Fig. 1. (× 19,000)

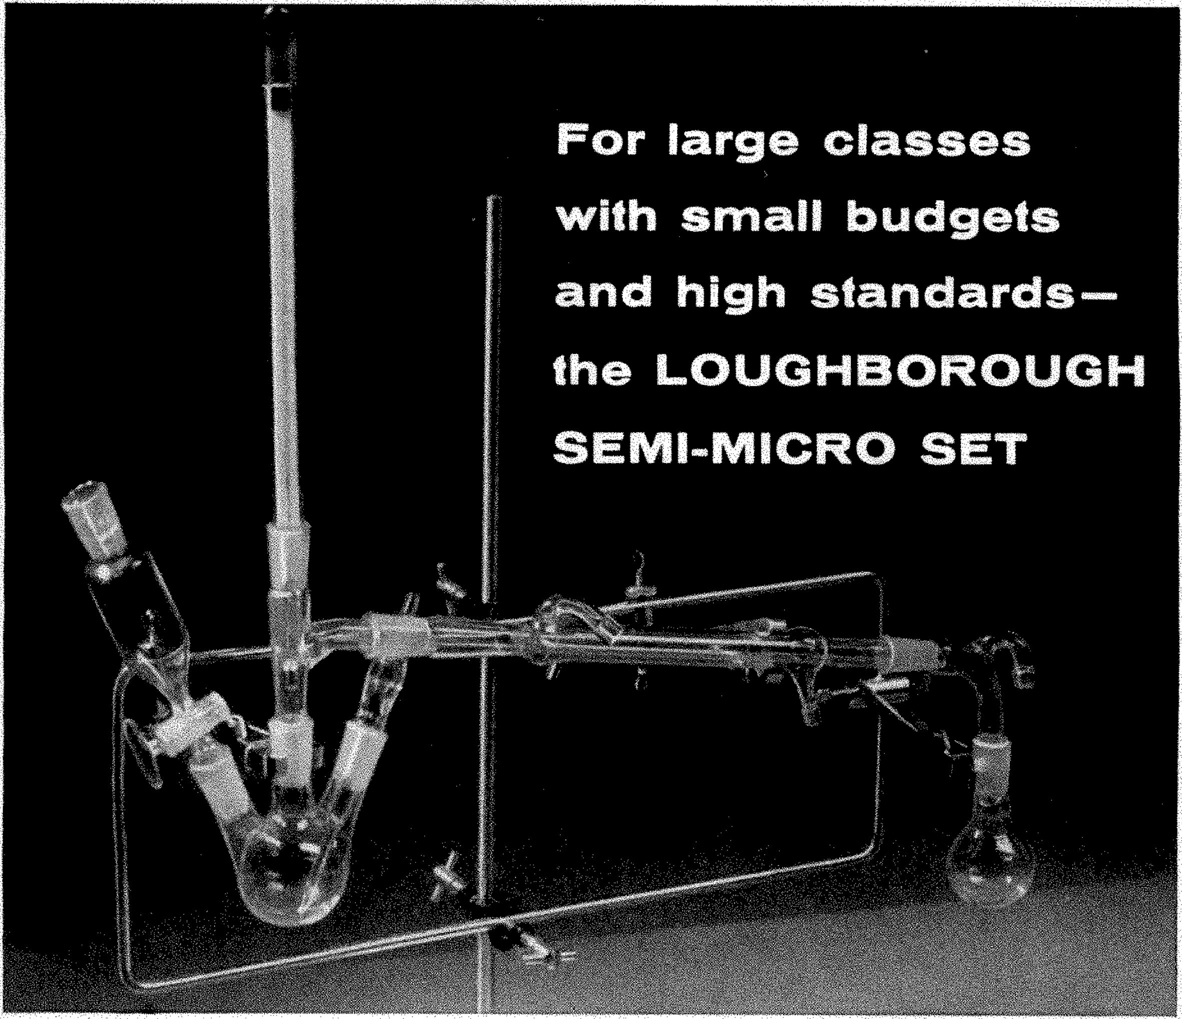

THE GLASSWARE IS ROBUST — The combination of round-bottomed flasks and B.14 joints throughout gives that extra strength, desirable in apparatus for educational laboratories, without sacrificing valuable economies in chemicals.

THE FIXING ASSEMBLY IS UNIQUE — The complete apparatus is firmly and safely carried on the framework, mounted on a single retort stand. The student lines up the apparatus as he would full-scale equipment — no predetermined positioning of clamps. Ordinary bunsen burners can be used and there is no fire risk — all fixings are metal.

THE SET IS VERSATILE — 15 operations can be carried out with this apparatus.

Write for details — there are alternatives provided to meet personal preferences and individual budgets.

THE STORY OF THE PERSIAN BEER BARREL

The fungus stereum subpileatum breaks down the cell structure of the wood

The mind of the beer drinker boggles indeed when he finds his pint smells of cheap scent . . . and that is what might have happened to many a man in the Spring of 1957, when he ordered X's Best Bitter.

The trouble was traced back to the barrels; the Persian oak from which they were made was infected with a fungus, living in the depths of the wood, that gave the beer its unwelcome perfume.

Oxoid Wort Agar then came into the story. Specimens of infected wood were incubated in the Agar, and tests were carried out to discover effective ways of killing the fungus. The normal steaming of staves would kill the fungus, but reinfection could occur from unheated heads of casks.

FOR PROGRESSIVE LABORATORIES, OXOID CULTURE MEDIA

The use of Oxoid Culture Media ensures constant quality and uniformity in your laboratory technique. Absolutely reliable, quick, convenient and economical, Oxoid Culture Media are available in tablet or granular form. Full details from: Oxoid Division of Oxo Ltd., Thames House, London, E.C.4 (CENtral 9781).

In Fig. 1 the oriented spermatid contains the mitochondrial nebenkern (N) at the posterior end of the nucleus, the proximal centriole lying in between. The distal centriole and the flagellum are at (C) and the Golgi body at (G). A further account of this work is being published elsewhere.

This work was performed in part under the auspices of the U.S. Atomic Energy Commission.

Synaptic Transmission in a Sodium-free Medium

The observation of Lorente de Nó[1], that small frog axons ("Et fibres") are excitable in media where the sodium is totally replaced by certain quaternary ammonium ions, has since been extended to crustacean muscle fibres[2], frog A-fibres[3,4], frog spinal ganglion cell-bodies[5] and mammalian striated muscle[6,7] and nerve[8] fibres. Such findings suggested that the membrane of muscle fibres and neurones in different species was capable of maintaining excitability when the external sodium was replaced by a favourable cation possessing a tetracovalent nitrogen atom. The purpose of the present study was to determine whether synaptic transmission could also be maintained in sodium-free media. It is well known that the membrane characteristics of the junctional region are somewhat different from those possessing the conductile activity, since the post-synaptic membrane produces graded responses by the action of the transmitter released from the pre-synaptic membrane. It was previously reported[9] that in the frog spinal ganglion cell-bodies hydrazinium ion was the most favourable substitute for sodium ion; the action potentials of cell-bodies being very similar to those observed in normal Ringer. An attempt to replace sodium ion by hydrazinium ion was quite successful; the neuromuscular transmission was restored in the sodium-free hydrazinium solution.

Nerve sartorius preparations of frogs (*Rana pipiens*) were used. The sodium-free hydrazinium solution contained 2 mM potassium chloride, 1·8 mM calcium chloride with various amounts of hydrazine (Eastman) and sufficient sucrose to maintain isotonicity. Both the hydrazine base and the final solution were adjusted to pH 6·5 with hydrochloric acid.

Neuromuscular transmission of the nerve sartorius preparations was completely blocked when soaked in a sodium-free 224 mM sucrose solution (containing 2·0 mM potassium chloride and 1·8 mM calcium chloride) for 30–40 min. In addition, the individual muscle fibres lost their electrical excitability, and the sensitivity of the end-plate membrane to directly applied acetylcholine was greatly depressed as measured by the absence of any contraction upon the application of acetylcholine in concentrations less than 10^{-5} gm./ml. No end-plate potential could be recorded by applying nerve stimulations. The disappearance of the end-plate potential caused by lack of sodium is mainly due to a decrease in the amount of released acetylcholine rather than a decrease in the sensitivity of the end-plate membrane to it[10]. It was quite certain, therefore, that the activity of the terminal endings of motor nerve fibres disappeared in a sodium-free sucrose solution, although the residual electrical activity of nerve twigs innervating the sartorius muscle was usually still detectable.

A surprising restoration of neuromuscular transmission occurred in the preparations which were first immersed in sucrose for 60–90 min. and then in a solution containing 80–100 mM hydrazine. Normal muscle contractions were induced by nerve stimulations about 10–20 min. after re-immersion in these solutions. Meanwhile, the resting potential of the muscle fibres maintained a normal value, and propagated muscle action potentials, similar to those observed in normal Ringer, were produced by intracellular direct stimulations. However, the values of the threshold of muscle fibres were considerably larger than those obtained in normal Ringer. With nerve stimulations the end-plate potentials could be recorded from the end-plate regions, and the propagated muscle spikes were observed from muscle fibres. The muscle contractions, however, disappeared shortly after continuous nerve stimulations (1/sec.) were applied for 10–20 min., although the electrical activity of the nerve twigs innervating the sartorius muscle and the sensitivity of the end-plate membrane were maintained (visible muscle contractions were produced by direct applications of acetylcholine in concentrations of 10^{-7}–10^{-8} gm./ml.).

These experimental results demonstrated that, in addition to the activity of the motor nerve axon[4], the activity of the muscle fibres with the post-synaptic membrane and of the motor terminal endings with the pre-synaptic membrane were also maintained in the sodium-free hydrazinium solution. Although a trace of sodium may be retained around the junctional regions, it is not likely that the concentration of sodium was sufficient to maintain transmission[10]. It seems as if the hydrazinium ion is acting in exactly the same way as the sodium ion does upon the post- and pre-synaptic membrane. The experimental evidence[11,12] obtained from spinal ganglion cell-bodies, however, seems to exclude this possibility. Recently, synaptic transmission in the sympathetic ganglion of frogs has also been found to be maintained in a sodium-free hydrazinium solution.

Effect of Tryptophan Analogues on Reversion of a Tryptophan-requiring Strain of *Escherichia coli*

Two years ago, Witkin[1] reported experiments indicating that protein synthesis was essential for the 'fixation' of the mutagenic state induced by ultra-violet irradiation. More recently, Doudney and Haas[2] have shown that at least two processes are involved in the production of bacterial mutations by ultra-violet irradiation; the first process results in fixation of the mutation into the genome, the second involves a removal of the mutagen produced by the radiation. We would like to report experiments that indicate that protein synthesis is involved in the actual utilization or degradation of the mutagen produced by ultra-violet irradiation.

Washed broth cultures of a tryptophan-requiring mutant of *Escherichia coli* strain *B/r* (isolated in this laboratory) were used in these experiments. Reversion of this mutant to the prototrophic condition was determined by plating cell suspensions on Petri dishes containing minimal medium. Ultra-violet irradiated cells, irradiated in buffer, were incubated for 1 hr. at 35° in 10 ml. of liquid medium of the indicated composition contained in centrifuge tubes (Table 1), they were then collected, washed and re-incubated for 1 hr. as indicated after which they were plated on minimal medium *C*[3]. Survival was determined by plating on minimal medium *C* supplemented with tryptophan. The amino-acid mixture (AA) was prepared according to Witkin[1] and contained no tryptophan. DL-Tryptophan, DL-5-methyl tryptophan and DL-tryptazan were added to give a concentration of 40 μgm./ml. The tryptazan was a gift from Dr. H. R. Snyder.

It is readily apparent that we have obtained the effect reported by Witkin; a large increase in the number of prototrophs was obtained by incubation immediately following irradiation in a medium rich in amino-acids. It is also apparent that the 'mutagen' produced by ultra-violet is stable when washed cells are incubated in medium with no tryptophan added or when 5-methyl tryptophan is added (Table 1). The mutagen disappears, however, following incubation with DL-tryptazan.

In order to make certain that the tryptazan effect is not due to a differential toxicity of this compound on the prototrophs, the following experiment was performed (Table 2). Irradiated cultures were incubated for 1 hr. in medium containing an amino-acid mixture with tryptophan added, after which the cultures were washed, incubated in minimal medium with amino-acids plus tryptazan for 1 hr., rewashed and plated on minimal medium *C*. There is no inhibitory effect of tryptazan on cells which have already been fixed by preliminary incubation in amino-acids plus tryptophan.

Table 1. EFFECT OF POST-IRRADIATION INCUBATION ON THE YIELD OF PROTOTROPHS. $6 \cdot 1 \times 10^8$ TRYPTOPHAN-REQUIRING *E. coli* PER ML. WERE IRRADIATED WITH ULTRA-VIOLET TO GIVE A SURVIVAL OF $4 \cdot 6 \times 10^7$ CELLS/ML. (7 PER CENT). ALL TREATMENTS WERE IN MINIMAL MEDIUM *C* SUPPLEMENTED AS INDICATED

	Post ultra-violet treatment	Viable cells plated	Mutants/plate	Prototrophs/10^6
	None	$4 \cdot 6 \times 10^6$	3·3	0·72
a	1 hr. AA, no tryptophan	$5 \cdot 2 \times 10^5$	1·0	2
b	As in (*a*), followed by an additional hour in AA plus tryptophan	$7 \cdot 7 \times 10^5$	97·6	127
c	1 hr. in AA plus tryptophan	$6 \cdot 3 \times 10^5$	126	200
d	As in (*c*), plus an additional hour in fresh medium of the same composition.	$8 \cdot 2 \times 10^5$	144	175
e	1 hr. in AA plus methyl tryptophan	$3 \cdot 8 \times 10^5$	6	16
f	As in (*e*), but followed by an additional hour in AA plus tryptophan	$5 \cdot 9 \times 10^5$	96·6	164
g	1 hr. in AA plus tryptazan.	$7 \cdot 0 \times 10^5$	0	0
h	As in (*g*), but followed by an additional hour in AA plus tryptophan	$5 \cdot 7 \times 10^5$	11	19

Table 2. EFFECT OF 5-METHYL TRYPTOPHAN AND OF TRYPTAZAN ON PROTOTROPH VIABILITY. $3 \cdot 5 \times 10^9$ CELLS PER ML. WERE IRRADIATED WITH ULTRA-VIOLET TO GIVE A SURVIVAL OF $4 \cdot 6 \times 10^8$ VIABLE CELLS PER ML. (13 PER CENT)

	Post ultra-violet treatment	Viable cells plated	Mutants/plate	Prototrophs/10^6
	None	$4 \cdot 6 \times 10^7$	1·3	2·9
a	1 hr. in AA plus tryptophan	$3 \cdot 1 \times 10^7$	198	640
b	As in (*a*), followed by 1 hr. in AA plus tryptazan	$2 \cdot 5 \times 10^7$	188	750
c	As in (*a*), followed by 1 hr. in AA plus 5-methyl tryptophan	$3 \cdot 4 \times 10^7$	159	470
d	As in (*a*), followed by 1 hr. in AA plus tryptophan	$2 \cdot 2 \times 10^7$	227	1,003

It is apparent that there is a striking difference in the effect of the tryptophan analogues 5-methyl tryptophan and tryptazan. In the presence of methyl tryptophan the 'mutagen' is stable, with tryptazan it disappears. We feel that this difference is related to the different use made of these analogues by *E. coli*. Tryptazan is activated by the amino-acid activating enzyme[4] and is incorporated into the protein of *E. coli*[5]. Methyl tryptophan is neither activated nor incorporated and in fact inhibits the activating enzyme. However, the proteins formed by the incorporation of analogues are often inactive biologically[6].

We suppose that the 'mutagen' produced by ultra-violet irradiation is consumed in some way as a result of the protein synthesis necessary for mutation fixation. Formation of an abnormal protein, with tryptazan substituted for tryptophan, results in disappearance of the mutagen, but without the production of mutations for which active protein is necessary. The mutagen is stable when protein synthesis is not possible, as in the presence of 5-methyl tryptophan.

We would like to take this opportunity to thank Drs. M. Lieb, E. Witkin and C. Doudney for making available a large amount of their results prior to publication. This investigation was supported in part by contract *AT*(30-1)1138 between Syracuse University and the U.S. Atomic Energy Commission.

Genotypic Control of Crossing-Over on the First Chromosome of *Drosophila melanogaster*

WHILE it has long been known that crossing-over varies both with the environment[1] and with maternal stage of development[2], relatively little is known about its genotypic control. Such information as exists is derived chiefly from the cytological observation of chiasma-frequency[3], although some is also available from the early work on *Drosophila melanogaster* by Gowen[4] and by Detlefson and Roberts[5]. Since cytological observations can rarely provide detailed information about the distribution of points of exchange along the lengths of single chromosomes, it was thought worth while to examine the genotypic control of crossing-over by the genetical study of recombination.

The experiment was designed to determine the effect of the autosomal genotype on the recombination between three marker genes on the X-chromosome, namely, white-eye (w), miniature wing (m) and bar-eye (B) (Fig. 1). Two long-inbred lines of *D. melanogaster*, Oregon (O) and Samarkand (S), together with their reciprocal F_1's, were chosen for this purpose. Using a balanced lethal stock CyL/Pm ; H/Sb, the marked X-chromosome was introduced into each of these inbred lines. The design of the experiment was that of an orthogonal three-point linkage test[6], and the estimation of recombination frequencies for each genotype in each of four environments (15, 20, 25 and 28° C.) was undertaken by Fisher's product method.

Fig. 1. Genetic map of the X-chromosome of *D. melanogaster*, showing the position of the three marker-genes. w, white-eye ; m, miniature wing ; B, bar-eye ; and C, centromere

The results of the experiment are shown in Fig. 2, from which three points emerge. First, Oregon has, on average, a higher frequency of recombination than Samarkand ; and the F_1, while consistently exceeding the mid-parent, nowhere exceeds both parents significantly, except in the case of the proximal segment at 25° C. The difference between the inbred lines is highly significant ($P < 0{\cdot}001$), as is that between the lines on one hand and their F_1's on the other. Since both the inbred lines may be regarded as virtually homozygous, it is clear that the variation of recombination-frequency with genotype is not solely determined by the degree of hybridity of the genotype, but also by its genic content. Nevertheless, it is equally clear that crossing-over can be related here to the heterozygous genotype, since the F_1's exceed the mid-parent in this respect. This is similar to the situation in rye as shown by Rees and Thompson (ref. 3*d*).

Secondly, the regional sensitivity of crossing-over to change in the environment varies markedly with genotype. Thus for Oregon and Oregon × Samarkand, the effect of change in the environment is more marked in the proximal than in the distal segment (when change is measured by the *maximum* difference between environments), and this is similar to the results of previous experiments[7]. Samarkand and Samarkand × Oregon, however, behave differently, for their frequency of recombination varies much less proximally than it does distally. The reason for this difference between the genotypes is not clear, since the marked X-chromosome is approximately the same in all. On the other hand, the similarity of the reciprocal F_1's with their respective maternal lines strongly suggests that the maternal cytoplasm determines, to some extent at least, the pattern of response of crossing-over to change in the environment. If, as Mather[8] suggests, high sensitivity to the environment is a property of the heterochromatic regions of the chromosome, then it may be that the distribution of heterochromatin varies with genotype. There is some evidence from certain Orthoptera that this can occur[9]. On the other hand, high sensitivity to the environment may not be confined to the heterochromatic segments of the chromosomes. A further possibility is that the difference between Oregon and Oregon × Samarkand, and Samarkand and Samarkand × Oregon in regional sensitivity may be due to differences in the distribution of their chiasmata along the length of the X-chromosome. The present observations provide no means of distinguishing between these hypotheses.

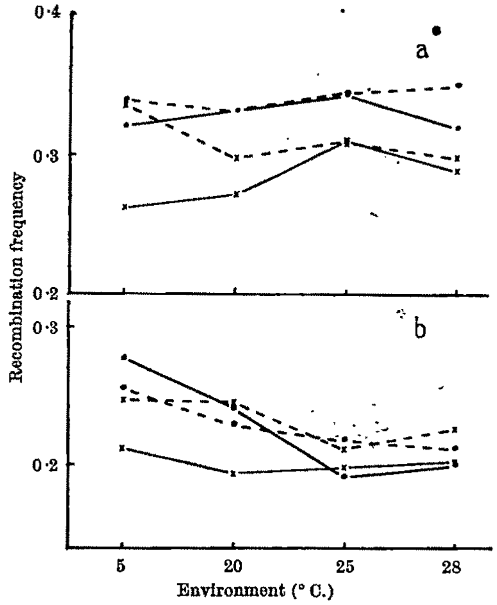

Fig. 2. Variation of recombination frequency of the (a) distal (w–m) segment and (b) proximal (m–B) segment with change of environment.

Oregon, ——·——; Samarkand, ——×——;
Oregon × Samarkand, ---·---; Samarkand × Oregon, ---×---

Thirdly, while there is a highly significant difference ($P < 0{\cdot}001$) between reciprocal F_1's in their frequencies of recombination between w and m, the difference between them is negligible in the proximal segment. The difference in the distal region is in the direction expected if maternal cytoplasm is active in determining crossing-over in this segment. But if maternal cytoplasm were the sole determinant, then we should expect the curves relating recombination to environment in the F_1's to be the same as those of their maternal parents. With the exception of the 25° C. environment, this expectation is clearly not realized. It is therefore evident that, in addition to the cytoplasm, the genotype must be having its effect in determining crossing-over in the distal as well as in the proximal segment.

Thus we can see that the genotype controls not only the gross amount of recombination, but also plays a part, together with the cytoplasm, in determining the pattern of response of meiosis to changes of environment. In other respects, the effect of the cytoplasm appears to be confined to a particular region of the chromosome.

I thank Prof. P. T. Thomas and Dr. A. Durrant for advice and guidance during the course of this work and Prof K. Mather for his help and criticism during the preparation of this report. The investigation was undertaken while in receipt of an Agricultural Research Council studentship.

Chromatid Breakage by Irradiation and the Oxygen Effect

SINCE the demonstration by Thoday and Read[1] that the yield of chromosome bridges and fragments produced in X-irradiated *Vicia faba* roots was influenced by the presence of oxygen during irradiation, more detailed investigations on the oxygen response of chromosome and chromatid aberrations have been carried out using *Tradescantia* microspores[2,3]. We have re-investigated the oxygen effect on the chromosomes of *V. faba* root tips, in order to make a detailed analysis of the influence of oxygen on the structure and frequency of the various chromatid aberrations induced by gamma-radiation.

Roots were irradiated with cobalt-60 gamma-rays using doses of 35, 78, 121 and 198r. in de-aerated (nitrogen) water and similarly, with the exception of the highest dose, in aerated water. The lowest two doses were given in 3·5 min. and the highest doses in 3·9 and 4·7 min. respectively. The amount of mitotic delay was known[4] and was insufficient to affect valid comparisons between treatments. The mean frequencies of true chromatid breaks, isochromatid breaks and chromatid interchanges, determined from roots fixed between 3½ and 5 hr. after irradiation, are shown in Fig. 1.

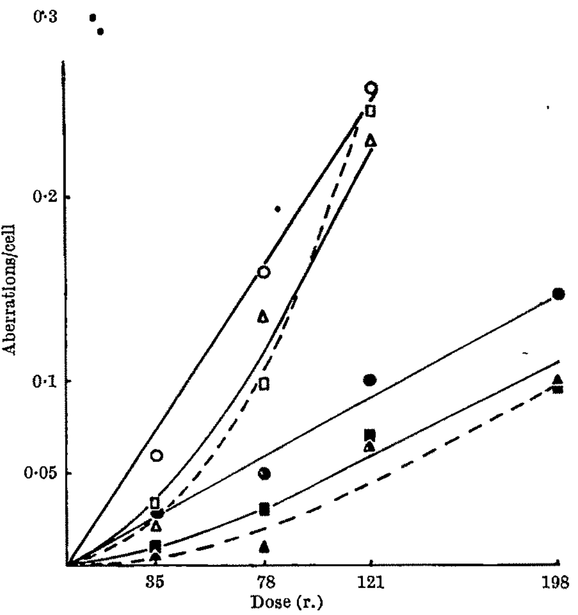

Fig. 1. Chromatid aberration frequency. Open symbols, air. Closed symbols, nitrogen. Mean chromatid break (—○—); isochromatid break (—□—) and interchange (– – – △ – – –) frequency for 400 cells at each point

The slopes of the curves relating frequency of aberration to dose have been determined and are given in Table 1. The results show that the presence of oxygen during irradiation increases the frequency of aberration, but does not change the shapes of the curves, the dose exponents in air and in nitrogen being similar (Table 1). As the shape of the dose-response curve for a given aberration is unaffected by the absence of oxygen, then the ratio of the doses in the absence and presence of air required to produce the same frequency of aberration is simply determined and is found to be the same for the three aberration types, nitrogen : air ~ 2·5 (Table 1). The nitrogen : air dose ratio for achromatic lesions, or gaps, is less than the ratio for the true chromatid aberrations, but there is no statistically significant departure from 2·5. The lower value of 2·1 is perhaps due to the fact that non-staining gaps are a heterogeneous mixture and are difficult to score objectively, especially at the highest doses used.

On the classical model that aberrations are produced by breakage and reunion of chromatids, perhaps the simplest interpretation of the constant dose ratio for the various aberration types, with and without oxygen, is that breakage rather than rejoining is affected. Cytological evidence in favour of this interpretation is obtained through comparing the frequencies of isochromatid and interchange aberrations which are incomplete, that is, those aberrations in which two ends remain unjoined[5]. The proportion of incompleteness found for isochromatid breaks and interchanges respectively was, in air, 30 ± 0·4 per cent and 34 ± 2·6 per cent, and in nitrogen, 35·5 ± 5·7 per cent and 35 ± 5·3 per cent. Thus there was no significant difference in incompleteness in air or nitrogen, a result also found by Conger[6] in X-irradiated *Tradescantia* microspores.

While the results support the view that oxygen increases the initial or primary effect of radiation on the chromosomes, certain details indicate that the primary event may not be the actual breakage of

Table 1. DOSE-RESPONSE EXPONENTS AND OXYGEN FACTOR FOR VARIOUS ABERRATION TYPES

Aberration	Gas	Dose exponent	Dose factor (nitrogen : air)
Chromatid breaks	Air	1·2 ± 0·13	2·51 (1·98–3·17)*
	Nitrogen	1·0 ± 0·12	
Isochromatid breaks	Air	1·5 ± 0·11	2·49 (1·98–3·15)
	Nitrogen	1·4 ± 0·18	
Chromatid interchanges	Air	1·9 ± 0·5	2·58 (1·91–3·50)
	Nitrogen	1·8 ± 0·28	
Gaps	Air	1·1 ± 0·07	2·13 (1·41–2·85)
	Nitrogen	0·7 ± 0·07	

* Fiducial limits at the 5 per cent level

chromatids. The low frequency of true chromatid breaks and the absence of isochromatid aberrations showing no reunion (*Nupd* types[5]) are more in accord with the exchange mechanism for aberration production, as proposed by Revell[7].

Further details and discussion of this work will be published elsewhere.

Nitrogen Fixation by Gram-Negative Bacteria

Although claims for nitrogen fixation by Gram-negative bacteria other than the *Azotobacter* have been made in the past[1], confirmation of such claims is comparatively recent[2-5]. Nitrogen fixation by particular strains of *Pseudomonas* has been reported by Anderson[2] and by Voets and Debacker[3]. Recently, Jensen[5] isolated from a Danish water-course a nitrogen-fixing organism that appears to be a species of *Achromobacter*. In most of these studies, the investigators were attempting to obtain species such as *Azotobacter* that are known to fix nitrogen; hence the techniques employed would select for this characteristic. Because of the significance of the discovery of these new agents for both theoretical and applied biology we have examined strains of *Pseudomonas* and *Achromobacter* that had been isolated under non-selective conditions.

Using the sensitive tracer nitrogen-15 technique as well as the more conventional Kjeldahl method, we have demonstrated aerobic fixation in six strains of *Pseudomonas* spp. and eight strains of *Achromobacter* spp. All the pseudomonads except *Ps. azotogensis*[3] also fixed anaerobically, but only Jensen's strain of the *Achromobacter* fixed in the absence of oxygen. The fixation process in both genera appears to be controlled by an inducible enzyme system.

The basal medium used throughout contained sucrose 2·0 per cent, disodium hydrogen phosphate 1·25 per cent, potassium dihydrogen phosphate 0·15 per cent, calcium chloride dihydrate 0·01 per cent, magnesium sulphate heptahydrate 0·01 per cent, ferric iron 0·0001 per cent and molybdenum (as molybdate) 0·00001 per cent. Ammonium nitrogen was added as required. Total carbohydrates were determined by the method of Morris[7], aeration values by the method of Cooper *et al.*[8].

Aerobic fixation and growth were studied in 100 ml. cultures in 500 ml. flasks, at 30° C., shaking at 350 r.p.m. on a Brunswick shaker with ¾-in. rotor; these conditions resulted in an aeration value of 0·315 mmoles of oxygen per litre per min. Initial and final aliquots were analysed for nitrogen and total carbohydrates. For the pseudomonads fixation varied from 3·0 to 50·0 μgm./ml. in 4 days, and the efficiencies of fixation from 1·1 to 4·3 μgm. of nitrogen per mgm. of carbohydrate used. Three phases of growth were evident: (*a*) an initial growth; (*b*) a lag phase; (*c*) a second growth phase. The extent of the initial growth depends on the quantity of ammonium nitrogen added to the medium; the lag phase probably reflects the synthesis of the enzyme system responsible for fixation; and the third phase is growth on molecular nitrogen. Analysis of the total increase of nitrogen in 25 ml. shake cultures indicated fixation of from 0·20 to 0·55 mgm. in 14 days. Incorporation of heavy nitrogen was demonstrated using concentrated suspensions of organisms harvested in the second growth phase. Exposure to an atmosphere of 10 per cent nitrogen containing approximately 36 atoms per cent excess nitrogen-15, 20 per cent oxygen and 70 per cent helium was made for 4 hr. at 30° C. in a well-shaken Warburg vessel; analyses showed a final incorporation of greater than 0·1 atoms per cent excess, for all cultures.

Achromobacter spp. showed the same type of growth characteristics; fixation was in the range 3·0–17·0 μgm./ml. in four days. The efficiency was of the order of 1·25 μgm./mgm. of carbohydrate used; nitrogen-15 incorporation ranged from 0·02 to 0·16 atoms per cent excess.

Anaerobically, fixation by the pseudomonads was of the order of 40 μgm./ml.; incorporation of heavy nitrogen was approximately 0·15 atoms per cent excess. The sole strain of *Achromobacter* that fixed anaerobically assimilated 39 μgm. nitrogen/ml., and contained 0·10 atoms per cent excess nitrogen-15.

In common with the nitrogen-fixing systems of other organisms, those in *Pseudomonas* and *Achromobacter* required a greater quantity of iron for the fixation of nitrogen than for growth upon ammonium-nitrogen. When fixing nitrogen, the strains examined possessed a hydrogenase demonstrable by the hydrogen–deuterium exchange reaction but not detectable by the evolution of hydrogen from reduced methyl viologen, or by the uptake of hydrogen on methylene blue.

This demonstration of nitrogen fixation by an apparently inducible enzyme system in a 'random' selection of strains of *Pseudomonas* and *Achromobacter* confirms and extends the investigations from the other laboratories. In the pseudomonads it provides yet another example of the adaptive versatility of the genus. Because of the widespread occurrence of both genera in soil and surface waters, their importance in nitrogen fixation may be considerable.

This research was supported in part by grant *E*-1417 (*C*4) from the National Institutes of Health.

Hydrogen Peroxide and Cancer

AFTER consultation with Holman, his experiment[1] was repeated as closely as possible in all details, except the strain of rat used, which was an inbred strain of Wistar origin. Experimental animals and controls carried tumours of the 9th, 10th, 11th and 15th successive transplants into this strain of a Walker carcinoma obtained from the Chester Beatty Research Institute. On the sixth day after inoculation, the drinking water of experimental animals was replaced by 0·45 per cent hydrogen peroxide in tap water. Tumours in experimental animals then ranged from 3·5 to 5·4 cm. longest diameter (mean 4·46 cm.), and in controls from 3·0 to 5·6 cm. (mean 4·48 cm.).

Of 20 experimental animals, 6 died of tumour in 18–36 days after inoculation, in 13 the tumour regressed completely in 17–60 days, and in 1, killed after 66 days, a residual tumour 1·1 cm. long was found. Of 20 controls, 3 died of tumour in 13–26 days, and in 17 the tumour regressed completely in 14–87 days after introduction.

Blood catalase and hæmoglobin values decreased as the tumours grew in size and rose again as they regressed. Blood catalase was approximately proportional to hæmoglobin, as found by Miller[2] for human erythrocyte catalase. The catalase/hæmoglobin ratio, however, tended to be higher for treated rats, with a wider scatter of values than in controls. The difference was not apparent until about a fortnight after the commencement of treatment; mean catalase/hæmoglobin ratios (ml. oxygen liberated per min./gm. hæmoglobin) for rats drinking peroxide for 18 days and more are 1,880 ± 244, and for untreated animals over the same period 1,719 ± 46; the mean difference is 161 ± 74, which has a probability of less than 1 in 20 of arising by chance.

Maximum growth of tumours which afterwards regressed was found at 7–24 days after inoculation, and in 20 of the total 31 regressions at 10–12 days. This appears consistent with an immunological mechanism of regression. Maximum tumour growth was slightly, but not significantly, less for treated animals than controls, and the mean weight of tumour-bearing rats at the time of maximum tumour growth differs significantly, being 193 ± 21 gm. for treated rats and 210 ± 29 gm. for controls—a mean difference of 17 ± 5 gm., with a probability of less than 1 in 100 of arising by chance. These findings are in accord with those of Ghadially and Wiseman[3], who also noted a smaller food intake by rats drinking peroxide. Chorąży *et al.*[4] report decreased liquid intake, which was found also in this experiment. Mean values of 120 observations on each group were 16 ± 4·2 ml. per day for treated rats and 24 ± 4·0 ml. per day for controls—a mean difference of 8 ± 0·3 ml., which is highly significant.

Drinking hydrogen peroxide thus appears to have two effects on the tumour-bearing rat. It slows down growth by reducing food and liquid intake, and it tends to raise the catalase/hæmoglobin ratio in the blood. No effect on survival was found in this experiment.

This work, which was designed as a pilot experiment, was aided by a grant from the University of Bristol Cancer Research Fund. I wish to thank Prof. A. Haddow for the gift of rats bearing the Walker carcinoma, Prof. J. S. Mitchell and Mr. E. A. King for advice and instruction in techniques, Miss E. H. L. Duncan for help with statistical estimations, Dr. C. H. G. Price for his continued interest and advice and Dr. R. A. Holman for discussions of his experiments.

A White-eyed Mutant Form of the American Cockroach, *Periplaneta americana* (L.)

WHITE-EYED mutants are well known in insects, but the majority of reported cases are confined to the order Diptera. Tate[1], in a paper on a white-eyed mutation in *Calliphora erythrocephala*, gives references to five other dipterans in which it has been known to occur, and more recently Paterson[2] has added another. Comparable mutations in other orders of insects seem to be less frequent, although the related phenomenon of albinism is known in the desert locust[3]. It may be of interest, in view of this, to report the occurrence of a white-eyed mutant form of the American cockroach, *Periplaneta americana* (L.).

This was originally found among a population of these cockroaches in a deep coalmine in Glamorgan and has been kept in pure culture in this Department for more than eleven years. The mutant character behaves as a Mendelian recessive, and observations on the laboratory stock indicate that it is not sex-linked; this point, however, needs further investigation.

During the past eleven years rough sampling of the cockroaches in the pit has been carried out from time to time, and the white-eyed mutants have been found to comprise about 5 per cent of the population. There has been no noticeable tendency towards any change in this proportion throughout the period. It is perhaps surprising that a mutant form should maintain itself at a substantially constant level for such a time, but presumably under mine conditions an unpigmented eye is a neutral character with no selective significance. The conditions of the population when the mutant form was spreading to its present numerical level are, of course, quite unknown. Cockroaches are said to have been present in the pit for a long time, but it is not known when white-eyed forms first appeared, and there is no reliable information about numerical fluctuations of the population as a whole.

In the course of a survey of the fauna of a number of South Wales coalmines, *Periplaneta americana* was found quite commonly, but only in the one pit were white-eyed mutants seen.

FORTHCOMING EVENTS

Tuesday, September 30

Society of Instrument Technology (at Manson House, Portland Place, London, W.1), at 6 p.m.—Prof. J. C. West: "Frequency Response Analysis Using Describing Function Method".

Wednesday, October 1

Institute of Petroleum (at 61 New Cavendish Street, London, W.1), at 5 p.m.—Mr. D. L. Pratt, Mr. G. M. Christie, Mr. E. F. Coxon and Mr. J. R. Lodwick: "Fuels and Lubricants for the Trans-antarctic Expedition"

Society for Analytical Chemistry (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6.30 p.m.—Mr. T. T. Gorsuch: "Application of Radio-Chemical Methods to the Recovery of Trace Elements".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. M. Smialowski (University of Warsaw): "Corrosion Embrittlement; the Effect of Cathodically Evolved Hydrogen on Iron and Nickel".

Royal Institute of Chemistry, London Section (at Eltham College, Grove Park Road, London, S.E.9), at 7.30 p.m.—Mrs. J. Holden, Dr. C. W. Herd, Dr. J. E. Salmon, Mr. P. A. Raine and Mr. W. H. Bennett: "Careers in Chemistry".

Thursday, October 2

Horticultural Education Association and the Association of Applied Biologists (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, South Kensington, London, S.W.7), at 11 a.m.—Joint Symposium on "The Relationships of Root to Shoot Growth in Plants".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. N. Hepper: "Botanical Expedition to Adamawa, British Cameroons"; Dr. H. B. D. Kettlewell: "Darwin and the Insects of Brazil" (a sound and colour film).

Society of Chemical Industry, Microbiology Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "Physical Methods in Microbiology".

Polarographic Society (at "The Duke of York", 8 Dering Street, London, W.1), at 7 p.m.—Informal Discussion Meeting on "Polarographic Problems in the Nylon Industry" introduced by Mr. R. D. Middleton.

Friday, October 3

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. B. A. Hems: "Cortisone from Hecogenin".

Saturday, October 4

Association of Clinical Biochemists and the Association of Clinical Pathologists (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2) at 9.30 a.m. and 2 p.m.—Scientific Meeting, including a Symposium on "Quantitative Paper Chromatography".

Nutrition Society (at the London Hospital Medical College, Turner Street, London, E.1), at 10.20 a.m.—Symposium on "Nutrition and Teeth".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Statistical Engineer (mathematician or statistician with a university degree in mathematics or statistics, and preferably a knowledge of meteorology) in the System Operation Branch, Central Electricity Generating Board Headquarters, London, S.E.1, for duties which include investigations requiring the application of advanced statistical and probability methods to engineering problems associated with the operation of a large interconnected electricity supply system, with particular reference to short-term load estimation and to the study of the effect of weather on system load—Personnel Officer, Central Electricity Generating Board, 24/30 Holborn, London, E.C.1, marking envelope "Confidential" and quoting Ref. No. N/268 (October 3).

Lecturer in Education—The Principal, Borough Road College, Isleworth, Middlesex (October 6).

Senior Lecturer or Lecturer (with a good honours degree and teaching experience) in Geography at Fourah Bay College (University of Durham), Sierra Leone—The Secretary, Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (October 6).

Research Student (with a good honours degree in zoology) in the Department of Zoology, for work in river ecology—The Secretary, The University, Exeter (October 10).

Assistant Lecturer (with special qualifications or interests in radio astronomy) in Physics—The Registrar, The University, Manchester 13 (October 11).

Lecturer or Demonstrator (with a medical or dental qualification or an honours degree in physiology or biochemistry) in Physiology—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (October 11).

Research Assistant (graduate) in the Department of Agriculture to carry out investigations into the efficiency of farm buildings by the application of work study methods—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (October 13).

Lecturer (preferably with interests and experience in protein and/or enzyme biochemistry) in the Department of Applied Biochemistry—The Deputy Registrar, The University, Birmingham 15 (October 15).

Research Physicist (preferably with experience in the use of ultra-high vacuum systems or in the chemical physics of surfaces) in the Department of Physics, for work which will involve electrical measurements applied to the study of surface contamination processes on semi-conductors—The Professor of Physics, University of Reading, Physics Research Laboratories, Upper Redlands Road, Reading, Berks (October 24).

Senior Lecturer in the Department of Mathematics, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, October 25).

Chair of Medicine tenable at St. George's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 28).

Scientific Officer (with a good honours degree and preferably two or three years postgraduate experience) in the Entomology Department to work on some problems concerning the biology of forest soils—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1051/12 (October 30).

National Coal Board Postdoctoral Fellow in Physical Chemistry to undertake research work connected with the study of solids by a number of techniques such as mass spectroscopy—The Registrar, The University, Birmingham 15 (October 31).

Principal (with high academic qualifications and appropriate educational and administrative experience) of the Northern Polytechnic—The Clerk, Northern Polytechnic, Holloway, London, N.7 (October 31).

Regius Chair of Botany in the University of Aberdeen—The Private Secretary, Secretary of State for Scotland, St. Andrew's House, Edinburgh 1 (November 10).

Research Fellow or Senior Research Fellow in the Colonial Products Council Natural Products Research Unit, Chemistry Department, University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 10).

Assistant (preferably with a science degree and a knowledge of languages) for Information Service for duties which include assisting with public relations activities, sub-editing, and internal information work—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks, quoting Ref. 58/25.

Chair of Metallurgy—The Secretary, The Royal College of Science and Technology, Glasgow.

Entomologist (with a good honours degree in natural science and some research experience in entomology) in the Agricultural Department, Trinidad, to carry out research on biology and control of insect pests of coconuts and to co-operate in assessing their importance as vectors of red ring disease—The Director of Recruitment, Colonial Office, London, S.W.1, quoting Ref. BCD.63/38/01.

Laboratory Technicians to work in the Physics Research Laboratories—The Bursar, The University, Reading.

Postgraduate Student (preferably with experience in systematic bacteriology, serology, or nutritional studies of bacteria) for research in the Bacteriology Department—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Research Physicist or Engineer (preferably with a knowledge and aptitude for hydrodynamics) to undertake model research on fluid flow—The Meteorology Department, Imperial College of Science and Technology, London, S.W.7.

Senior Lecturer in Applied Physics; a Lecturer in Physics; and an Assistant (Grade B) for Mathematics—The Clerk to the Governors, Mid-Essex Technical College, Market Road, Chelmsford, Essex.

Senior Plant Breeder (with a good honours degree in botany and postgraduate experience in the technique of plant improvement) at the West African Cocoa Research Institute, to carry out research on plant breeding problems relating to cocoa and to plan and take charge of the work of the Plant Breeding Section of the Institute, serving initially at Tafo, Ghana—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/200/024.

Senior Scientific and Scientific Officers (with a first- or second-class honours degree in physics, mathematics or engineering or equivalent) at the Government Communications Headquarters, Cheltenham, for telecommunications and electronic research in the following fields: V.H.F. receiver design and microwave techniques, propagation trials; applications of semi-conducting devices; high speed electronic switching; data storage and handling; computer programming, and operational research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A147/8A.

BUTTERWORTHS SCIENTIFIC PUBLICATIONS

Publishers to the International Union of Pure and Applied Chemistry

We proudly announce this new association between one of the foremost International Scientific Unions and Butterworths Scientific Publications.

IUPAC activities extend over the whole range of organic and inorganic chemistry. Records of its transactions will be of ever increasing importance to the research team and to their librarian. You will be advised through the pages of 'Nature' and by direct mail as each new publication appears.

By this recent agreement the International Union of Pure and Applied Chemistry has paid a signal honour to British publishing. In particular it acknowledges the standard of publishing which has made Butterworths more than a name . . . a publishing tradition.

Publishers to the International Union of Pure and Applied Chemistry

LECTURES AND COURSES

PORTSMOUTH COLLEGE OF TECHNOLOGY

DEPARTMENT OF CHEMISTRY AND BIOLOGY

SANDWICH COURSE IN CHEMISTRY

For the third consecutive year the Sandwich Course in Chemistry will be held, commencing in September, 1958. The Course prepares for the examinations leading to the Graduateship of the Royal Institute of Chemistry. The Course (Works-based and College-based) is of four years' duration and involves six months' study at College each year. The normal requirements for admission will be passes at "A" level (G.C.E.) in chemistry together with physics and/or mathematics, or a national certificate in chemistry. Some vacancies still remain. Inquiries from industrial firms, government departments and individual students welcomed.

Particulars from the Registrar, College of Technology, Park Road, Portsmouth.

UNIVERSITY OF LONDON: A COURSE OF two lectures entitled (i) "The Postulate of Invariance in Evolution"; (ii) "The Cortical Correlate of Perceptual Organization" will be delivered by Professor W. Köhler (Princeton) at 5.30 p.m. on October 7 and 9 at University College (Physiology Lecture Theatre), Gower Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar.

OFFICIAL APPOINTMENTS

FEDERATION OF NIGERIA

DEPARTMENT OF AGRICULTURAL RESEARCH

Agricultural specialist staff are required as follows: Plant Breeders. To undertake research on rice and legume crops. Plant Pathologists. To study crop plant diseases and devise means for their eradication or control. Agronomists. To assess problems of field husbandry and to assist in the economic application of the results of research on coffee, kola, fruit, rice, and legume crops. Horticulturist or Economic Botanist. To plan the introduction and exploitation of plants of economic importance to Nigeria. Microbiologist and Chemist. To carry out team research into improvements of soils and crops under high rainfall conditions. Analyst. To carry out analysis and testing of soil and plant materials in connection with the research programme of the soils and crops nutrition team and to supervise the routine work in the Chemistry Laboratory. Animal Geneticist. To advise on the animal breeding policies of the Regional Departments of Agriculture. Candidates must, in all cases, have a good honours degree in the appropriate subject with suitable postgraduate experience or training. Appointments on contract/gratuity terms with emoluments in scale £966 to £1,824 per annum. Gratuity of £25 to £37 10s. for each completed period of three months' satisfactory service. Outfit allowance £60. Free return passages for officer, wife and children up to equivalent of four adult passages in all. Furnished quarters, usually available, at moderate rental.

Apply, giving brief particulars to, Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/14/02.

UNIVERSITY OF HONG KONG

SENIOR RESEARCH OFFICER OR RESEARCH OFFICER IN THE FISHERIES RESEARCH UNIT

Applications are invited for this post within the Department of Zoology. Annual salary (superannuable) is: Senior Research Officer: £2,000 by £75 to £2,300 or Research Officer: £1,575 by £50 to £2,175. There is also an annual expatriation allowance of £250 or £225, depending on the scale to which the successful applicant is appointed. The equivalent of income tax in the Colony is comparatively low. First-class sea passages are provided for expatriate staff and their families on first appointment and leaves. Furnished accommodation is provided for expatriate staff at reasonable rents. Applicants should be men who are qualified zoologists with experience of fisheries research. The successful applicant will be required to take up his duties on January 1, 1959.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Hong Kong and London, is October 30, 1958.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3

DEPARTMENT OF CHEMISTRY

The Governors invite applications for the following posts: (a) Senior Lecturer in Analytical Chemistry with special experience of some aspect of this subject, e.g., the Analysis of Food and Drugs, or Micro-analytical Methods. Industrial or research experience is essential. (b) Lecturer with special interests in Physical Organic Chemistry and with postgraduate experience in this field. (c) Lecturer with special knowledge of Theoretical Inorganic Chemistry and with postgraduate experience in this field. (d) Lecturer or Assistant Lecturer in Organic Chemistry with postgraduate experience. For appointments (b), (c), (d) (except that of Assistant Lecturer) some previous teaching experience is regarded as essential. The appropriate salary scales for men are as follows: (i) Senior Lecturer, £1,350 by £50 to £1,550; (ii) Lecturer, £1,200 by £30 to £1,350; (iii) Assistant, Grade B, £650 by £25 to £1,025, plus additions for training (£25 to £75); graduate status (£75); good honours degree (£50), and London allowance of £36 or £48 according to age. The salary scales and additions for women are slightly less than those for men but are subject to equal pay increments leading to equalization as from April 1, 1961.

Particulars and forms of application from the Clerk to the Governors, to whom applications should be submitted by October 13, 1958.

RADIOCHEMICAL CENTRE

AMERSHAM

has vacancies for

TWO ORGANIC CHEMISTS AND A BIOCHEMIST

to work on the labelling of complex compounds with radioactive isotopes.

Applicants should possess at least a first- or second-class honours degree and have a special aptitude for exacting preparative chemistry.

Appointments will be made as Scientific Officers (£645 to £1,120) or Senior Scientific Officers (£1,215 to £1,425) with good prospects of promotion to higher posts, under the standard conditions of service in the United Kingdom Atomic Energy Authority.

Apply to the Personnel Officer (1225Y/34), The Radiochemical Centre, Amersham, Buckinghamshire.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in Physics with special qualifications or interests in radio astronomy. Salary scale £700 to £850 per annum with membership of the F.S.S.U. and Children's Allowance Scheme.

Applications should be sent not later than October 11, 1958, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

WELSH COLLEGE OF ADVANCED TECHNOLOGY

REGIONAL TECHNICAL INFORMATION OFFICER

Applications are invited for the post of Regional Technical Information Officer, to be based on the College. Applicants should be qualified in pure or applied science with a broad background of knowledge and experience. In the first instance the post is temporary for eighteen months. The salary offered will be between £1,350 to £1,550, depending upon qualifications and experience.

Further particulars may be obtained from the Principal, at the College, Cathays Park, Cardiff.

ROBERT E. PRESSWOOD,
Clerk to the Governors.

City Hall, Cardiff.

APPLICATIONS ARE INVITED FOR THE post of Physiologist (or Pharmacologist) with the Medical Research Council in the Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford. The applicant should have a Ph.D. or equivalent experience of research. Research is contemplated into various problems connected with neurohumoral physiology. Experience in pharmacological assay, experimental physiology or electro-physiology is desirable. Salary approximately £1,150. The post comes under the F.S.S.U. for superannuation.—Applications to be sent to the Regius Professor of Medicine at the above address.

NIGERIAN COLLEGE OF ART SCIENCE AND TECHNOLOGY

Principal: C. A. Hart, C.M.G., T.D., D.S Ph.D., M.I.C.E., M.I.Mech.E., F.R.I.C A.M.I.Struct.E.

Applications are invited for the posts (a) Senior Lecturer in Applied Mathematics (b) 2 Lecturers in Mathematics. Qualificatio Good honours degree and teaching experie Salary scale (Pensionable): (a) Grade II, £1,41 £1,740 per annum or Grade I, £1,800 to £1 per annum; (b) £804 to £1,690 per annum cluding inducement addition for overseas ca dates. Entry point according to experie Appointment on contract at 10 per cent hi basic salary plus gratuity £100 to £150 per an can be made if preferred. Partly furnished h at moderate rent; 7 days' leave, normally ta annually, for each month of resident ser Free first-class passages. Children's U.K. m tenance grant up to £150 annually and pass assistance. Free medical attention.

Applications (six copies), giving age, quali tions, experience and names of three refe should be sent to The Council for Ove Colleges, 12 Lincoln's Inn Fields, London, W. Closing date October 6, 1958.

Middlesex County Council Educati Committee

BRUNEL COLLEGE OF TECHNOLOGY

WOODLANDS AVENUE, ACTON, W.3

There are the following three vacancies lecturers at the College, each post being with the Burnham Scale range £1,236 to £1,398 annum.

1. LECTURER IN SPECTROSCOPY to tea the subject in courses for the Diploma in Tec nology. Degree and professional qualificatio necessary, and the person appointed may be quired to give assistance with the teaching Physical Chemistry. Ability to advise resea students in the use of spectroscopic techniq desirable.

2. LECTURERS IN ELECTRONICS (2 po in the Department of Electronics to teach subject in its physical and applied aspects. T Department is responsible for the teaching Electronics throughout the College. A go understanding of the fundamentals of electroni industrial or research experience is necessary a university or technical college experience desira but not essential.

The College, which occupies very pleas modern buildings, is new and developing rapid it offers courses for the Diploma in Technolo University of London degrees and other qu fications. There are many interesting educatio problems associated with its new courses. C contact is maintained with industry and major research organizations, and every encour ment is given to staff to undertake research.

Those interested in the above posts should at once to the Principal.

C. E. GURR, M.Sc., Ph.D
Clerk to the Governing Bod

UNIVERSITY OF READING

Research Assistant wanted for work on physiology of flowering in carnations. The appo ment would be, in the first instance, for one only. Candidates should have a good first de in botany or horticulture; research experience a higher degree an advantage. Salary betw £450 and £600 per annum according to age experience.

Applications to Professor O. V. S. Hea Department of Horticulture, The Univers Reading.

SENIOR SCIENTIFIC AND SCIENTI Officers, required at Government Communicati Headquarters, Cheltenham, for telecommunicati and electronic research in following fields: V.F receiver design and microwave techniques; pro gation trials; applications of semi-conducting vices; high speed electronic switching; data s age and handling; computer programming, operational research. Candidates must norm be natural born British subjects of natural British parents. First- or second-class hon degree in physics, mathematics or engineering equivalent, at least three years' postgraduate perience for Senior Scientific Officer. Salaries men (provincial rates) Senior Scientific Offic £1,130 to £1,330; Scientific Officer, £595 to £1,0 (according to age and qualifications). Appoi ments unestablished but opportunities to comp for established posts.—Forms from Ministry Labour and National Service, Technical and Scie tific Register (K), 26 King Street, London, S.W quoting A147/8A.
